Note—Illustrated articles are marked with an (*) asterisk, editorials with an (E), letters to the editors with an (L), questions and answers with a (Q), paragraphs with a (P), and news items with an (N).

A

A change of attitude (E).....	255
A direct course is a direct saving. Robert B. Lea	*361
A great loss: Death of President Harding (E).....	517
A real opportunity (E).....	650
A real saving (E).....	453
A reflex of the defeat of the ship subsidy bill (E)	322
Ackerson, J. L.: Selection of best kind of propelling machinery	167
Adda, Passenger motorship.....	*31
Additional notes on American shipyard apprenticeships, evening schools and scholarships. C. F. Bailey.....	747
Admiral Bettolo, Italian steamship launched (N)	579
Admiralty decisions, Current. C. B. Gill, 309, 337, 375, 441, ...	579
Aeroplane view of United States aeroplane carrier Langley (photograph).....	*558
Agamemnon and Mt. Vernon (E).....	194
and Mount Vernon, Disposition of ex-German transatlantic steamships.....	*591
Air gun: Jenkins Bros.....	46
Airplane carriers building for U. S. navy, Powerful	*29
lands on deck of United States warship (photograph)	*16
Air pump for marine service, Radojet: C. H. Wheeler Mfg. Co.....	*691
Albert Ballin, Passenger steamship.....	*48
Ballin, Twin screw turbine steamer. E. Foerster	*457
Alexander Hamilton, Hudson River Day Line steamer (N).....	715
Allegheny and Berkshire, Passenger and freight steamships	*329
America becomes largest cabin ship afloat. Reconditioning and conversion of steamship (N)	247
saves 1,400 tons of coal, steamship.....	*73
will fight for place on the high seas. "Old Scotch"	416
American Balsa Company, Inc.: Nesting lifeboat	*34
Welin marine type releasing gear.....	*215
American Brass Company: New lead covered cable	738
American Engineering Standards Committee (P)	53
American Legion pledges aid for up-building of merchant marine.....	695
American Marine Association announces plan for marine show (N).....	575
elects officers for the coming year.....	*787
spring banquet (N).....	249
American marine congress (E).....387, 249,	721
adopts resolutions outlining constructive policy for merchant marine.....	*729
called (N)	444
grows bigger and bigger.....	522
Secretary Hoover to preside at	589
to become a permanent body (N).....	788
to feature Marine Week of 1923.....	*681
American Marine Standards Committee meets	*256
ready for action.....	411
American passenger ships setting a high standard. James Swan.....	*654
American ships carry less than 25 percent of overseas commerce of the United States	652
American Society of Mechanical Engineers, Spring meeting (P).....	308
American Strombos Company, Inc.: Air-driven marine signal.....	*119
American trade needs American ships. E. C. Plummer.....	*651
American Wireold Company: New conduit for electric wiring.....	*28
An imperative demand (E).....	517
Analysis of claims of the electric drive over the geared drive. J. C. Shaw.....	*417
Anchors and chain cables, Book on (Q).....	505
and chain, Materials for (Q).....	505
Ann Arbor car ferry No. 3 lengthened.....	*207
Annin, R. E.: Curious incidents in the careers of hoodoo ships.....	74
Anti-rolling tanks, New System of Frahm. Applications of arc welding to ship construction. E. H. Ewertz, ...	*48
*420, 480, 549, 625, ...	774

Apprenticeships, evening schools and scholarships, Additional notes on American shipyard. C. F. Bailey.....	747
Arc welder for ship work and new galley range: Todd Shipyards Corporation.....	*740
welding to ship construction, Applications of. E. H. Ewertz, ...	*420, 480, 549, 625, 774
Arizcna, Motorship	*34
Army launches first all-electric dredges.....	763
Ash, influence of in coal on boiler efficiency (Q)	784
Asphalt decking, New: James Coffey Engineering Corporation	736
Association, North Atlantic Ports (N).....	187
Atlantic Coast Shipbuilders' Association, Removal of (P).....	503
Coast Shipbuilders to meet on May 14 (N)	248
Transport passenger liner Minnewaska.....	*613
Waterways Association, Convention of (N)	642
Automatic control for cargo winches: General Electric Company.....	736
feed water regulator: Babcock & Wilcox Company	*734
steering. E. T. Sederholm (L).....	311
steering, Wake system of. R. H. Rogers	*173
Automobile-carry fleet developed on Great Lakes. A. C. Jackson.....	*496
Australian government shipping venture costly (N)	645
Auxiliary Diesel yacht Hussar.....	*341
sailing houseboat Moby Dick launched (P)	456
Auxiliaries, electric, an economic necessity. Walter Thau	*276
Aviation, Comments on naval and commercial. E. S. Land	748

B

Babcock & Wilcox Company: Automatic feed water regulator.....	*734
Concentration salinity indicator.....	*41
Mechanical atomizing oil burner.....	*690
Mechanical oil burner.....	*556
Oil burner for Scotch boilers.....	*117
Bailey, C. F.: Additional notes on American shipyard apprenticeships, evening schools and scholarships.....	747
Bake oven, Westinghouse electric.....	*619
Balance, Improved sash: O. M. Edwards Company, Inc.	742
Ballast pumping systems developed, New. Balsa-Welin nesting lifeboat.....	*34
Barge contract, American Bridge Company (N)	712
designed for excavation work, derrick.....	*211
Self-discharging (P)	524
Barges, Electric contract for Diesel (N).....	189
for Government, Six Wheel (N).....	641
for Portland, Ore., Six steel (N).....	643
Three S. O. Diesel oil (N).....	712
Barrels of oil per knot (Q).....	637
Basic design problem (Q).....	376, 505
Bates, James L.: Efficient ships are those best meeting requirements.....	474
Battle destroyer No. 16, Japanese (photograph)	*104
Battleship Colorado, U. S.	*605
Indiana, partially completed (photograph)	*601
West Virginia goes into commission.....	*783
Bearing metal introduced to marine service Bearings, Rubber surface cutless: B. F. Goodrich Company	426
*692	
Belgenland on her maiden voyage, Passenger steamship (N).....	*315
Belgian mail ships for service to Africa. Bennett, E. C.: Deadweight.....	*209
76	
Berkshire launched, Steamship (N).....	249
Bethlehem Shipbuilding Corporation: Furnace front for Dahl oil burner.....	*360
*738	
Plant mills direction indicator.....	*693
Self-contained oil pumping outfit.....	*111
Biles, Sir John H.: Stability of large ships Bituminous coatings for shipbuilding purposes. H. H. Thayer.....	369
Blacker Engineering Company: Power driven hammer	*491
Block coefficient, Formula for (Q).....	637
coefficients and proportions of merchant steamships. W. J. Lovett.....	115
Blocks, ropes and chains for shipbuilding purposes. H. H. Thayer.....	43

Boiler and engine room, Tuning up the. William Bunker	*281, 365
efficiency, Influence of ash in coal on (Q)	784
Boiler feed, Salt water unsuitable for (Q)	505
gives 85 percent efficiency, Oil-fired Scotch. C. J. Jefferson.....	*615
Improved Foster watertube.....	*352
requirements for marine engine (Q).....	184
room economies, Modern, J. J. Nelis.....	271
Special working pressure of Scotch (Q).....	184
water gage glass, Strength of (Q).....	784
Boilers, Care and upkeep of marine watertube. A. Ross Mackay.....	433
in France, Testing marine. A. M. Thachara	234
Book on anchors and chain cables (Q).....	505
"Bordereaux": Developments in marine insurance.....9, 78, 147, 205, 307, 373, 436, 501, 568, 635, 708, ...	781
Bottom compositions. H. H. Thayer.....	570
Bow wave length and contour, Formula for (Q)	442
Brake, All-steel power press: Cincinnati Shaper Company	*100
British-built Diesel electric ship completes trials, First. Special London Correspondent	*706
British marine oil engines developed. Special London Correspondent.....	*566
shipbuilding lowest in 30 years.....	216
shipbuilding outlook much brighter. W. H. Wendon	145
shipping and shipbuilding developments. W. H. Wendon.....	371
shipping and shipbuilding in 1922. W. H. Wendon	14
Shipping Exhibition (N).....	248, 645
shipowners face keen competition abroad. W. H. Wendon.....	704
shipyards get string of new contracts. W. H. Wendon.....	303
Brown Instrument Company: Salinity meters	*744
Bulbous bow on resistance, Influence of the. D. W. Taylor.....	*540
Bunker oil, System for handling from storage: Row and Davis Engineers, Inc.	*49
Bunker, William: Tuning up the engine and boiler room.....	*281, 365
Bureau of Navigation report for August (P)	601, 641

C

Cable, New lead covered: American Brass Company	738
ship Marie Louise Mackay, New.....	*18
ship Store Nordiske, New oil-fired (photograph)	*21
steamer Dickenson launched (P).....	174
Calculations for cooling surface of condenser (Q)	121
Canal at New Orleans, New inner-harbor navigation (P)	271
Car ferry for Missouri-Illinois railroad.....	*162
ferry George H. Walker goes into service (N)	715
ferry launched on Ohio river, Mammoth.....	*338
Care and upkeep of marine water-tube boilers. A. Ross Mackay.....	433
Cargo conveyor, Telescopic.....	*604
motorship Arizona	*34
winches, Automatic control for: General Electric Company	736
Cargoes increasing, Intercoastal.....	539
Cast iron couplings, Shrinking on steel shafts (Q)	120
Castings for ships, Manufacture of heavy steel. H. P. Frear.....	754
Chain cable, Life of (Q).....	573
Chains, ropes and blocks for shipbuilding purposes. H. H. Thayer.....	43
Chamber of Commerce meeting (P).....	300
of the United States, Annual meeting of (N)	248
opposes Government operation of ships (N)	382
urges Senate to grant Government aid to shipping (E)	2
Chamber of shipping discusses maritime situation. W. H. Wendon.....	200
Chapman, L. B.: Comparison of steamships and converted motorships.....	137
Does an annual saving of \$40,000 interest you?	*197
Effect of stevedoring costs on operating expenses	71

- Chapman, L. B.—Continued
Influence of speed on economy of motorships 435
Relative economy of steam and motor vessels 38
Chicago Pneumatic Tool Company: Flexible couplings for direct motor drive compressors *230
Chief engineers on Shipping Board honor list (N) 640
Cincinnati Shaper Company: All-steel power press brake *100
City of Chattanooga, Passenger steamer... of Nagpur, Passenger and cargo steamship *81
Clearances for pins and journals (Q)..... 442
Clermont, Replica of (photograph)..... *234
Cleveland bought by United American Lines, Steamship (N)..... 510
to be converted to an oil burner (P)..... 556
Clipper stem, Why naval vessels have a (Q) 310
Clyde Line steamers, Bids for (N)..... 509
Line, Two Type "B" steamers for (N)..... 577
CO₂ recorders, Use of (Q)..... 573
Coast service, United American Lines inaugurated new 520
Coastwise steamships Alleghany and Berkshire *329
Coefficient, Length for "full" (Q)..... 506
Coen Company: Mechanical oil burner with self-seating holder *694
Coffey Engineering Corporation, James A.: Fiber flooring for ship decks..... *114
New Asphalt decking 736
Colorado nearing completion, U. S. battleship (photograph) *241
the World's mightiest superdreadnaught (photograph) *565
United States battleship..... *605
Combined riveting and welding (E)..... 389
riveting and welding, N. G. Near (L)..... 574
riveting and welding, J. W. Owens (L)..... 710
Comments on aviation—naval and commercial, E. S. Land..... 748
Committee to cooperate with Department of Commerce (P) 728
Comparison of steamships and converted motorships, L. B. Chapman..... 137
Comparative fitness of afterbody of submarine destroyer (Q)..... 709
Competition for ship repair contracts in Europe, W. H. Wendon..... 492
in overseas shipping met by using efficient ships and propelling machinery, A. S. Hebble..... 679
Compositions, Bottom, H. H. Thayer..... 570
Compound engine, Figuring indicated horsepower of (Q)..... 784
Compressor unit, Motor: Hill Rotors, Inc., Compressors, Flexible couplings for direct motor drive: Chicago Pneumatic Tool Co. *230
Concentration salinity indicator: Babcock and Wilcox Company..... *41
Condenser, Calculations for cooling surface of (Q) 121
tubes, Failure of W. R. Webster..... *771
Conduit for electric wiring, New: American Wiremold Company..... *28
Congress, American marine..... 522
American marine (E)..... 387, 649, 721
Delaware River district committee, Marine (N) 576
Diesel engine committee organized for Marine (N) 575
frames shipping policy, Marine..... *729
Secretary Hoover to preside at American marine 589
to become a permanent body, American Marine (N) 788
to feature Marine Week of 1923, American marine *681
Connecting shackles, Improved: National Malleable Castings Company..... 736
Consolidation of war and navy departments proposed (P) 49
Construction, Application of arc welding to ship, E. H. Ewertz.*420, 480, 549, 629, Marine work of all classes reported (P), news, Marine (N)..... 318, 384, 449, 514, 580, 646, 718, 792
report of Bureau of Navigation to August 1 (N) 641
The trend in Great Lakes ship..... *425
Conte Verde, Passenger steamship..... *342
Conti, Angelo: What part will motorships play in our shipping?..... *671
Contracts, British shipyards get string of new, W. H. Wendon..... 303
Control station for dredge: Westinghouse Electric & Manufacturing Company..... *738
Convention of Atlantic Waterways Association, Annual (N)..... 642
of Society of Naval Architects and Marine Engineers, Annual..... 747
Conversion to motorships (P)..... 204
Conveyor, Telescopic cargo..... *604
Cooperation along Atlantic seaboard proposed (E) 67
between owner, builder and operating personnel, Marine Engineer (L)..... 785
of shipping industry (N)..... 246
Corsair converted to an oil burner, Steam yacht (N) 576
Cost of operation, Situation demands reduction in, "Old Scotch"..... 259
of ship repairs, Eads Johnson (L)..... 506
Couplings, Bibby flexible: Falk Corporation *742
Course in Gyro Compass for British officers (P) 525
Crandall 4,000-ton railway dry dock..... *163
Crane at Boston Army Base, Largest in world (photograph) *23
Crook shipyard sold (P)..... 520
Cruiser Omaha, Trial run of..... *109
Crux, Motorship *599
Curious incidents in careers of hoodoo ships, R. E. Annin..... 74
Current actuated or Flettner rudder..... *231
- D**
- Dahl oil burner, Furnace front for..... *360
Dalgoma, Sulzer two cycle engine motorship, Our Special London Correspondent *429
Data sheet: German liner Albert Ballin E. Foerster 462
passenger steamship America..... 471
passenger steamship President Buchanan, steamship Halekale 218
steamships Alleghany and Berkshire..... 155
tank-motorship Oljaren *334
Wilson Line excursion steamers..... *87
Davis, M. C.: Why Americans pay greater Panama canal tolls..... 527
Deadweight, E. C. Bennett..... *609
Decking, New asphalt: James Coffey Engineering Corporation 76
Defeating its own object (E)..... 193
Definite shipping policy still under consideration (E) 194
DeLaval Steam Turbine Company: Multistage centrifugal pump..... *110
Delaware River district committee of Marine Congress (N)..... 576
Denby, Edwin: Navy and merchant marine are interdependent *657
Depreciation of steel ships, Rate of (Q)..... 637
Depression leads British to urge Government aid, Special English Correspondent 559
"Der Tag" (E)..... *2
Derrick barge designed for excavation work, Designing the marine power plant for efficiency, W. B. Flanders..... *211
Determining the strength of a hollow shaft and coupling (Q)..... *292
Detroit, Official trials of scout cruiser..... 242
Development in marine boilers, New..... *431
Developments in marine insurance, "Bordereaux"..... *352
..... 9, 78, 147, 205, 307, 373, 436, 501, 568, 635, 708, 781
Deviation charges (E)..... 454
Devices shown at the Marine Exposition, New *689
DeWitt Clinton converted to oil burner, Steamer *415
Diameter of engine shaft (Q)..... 184
Diamond Power Specialty Co.: Rear end front-operated soot blower..... *734
Dickenson, Cable supply ship..... *92
Diehl Manufacturing Company: Gyration electric ceiling fan..... *738
Diesel and the future, The, K. H. Donavlin (L) 638
auxiliary schooner yacht Hussar IV..... *602
drive, Conversion of tonnage to (E)..... 650
electric drive: Trials of motorship Standard Service *340
electric motorship Twin Ports (N)..... *640
electric pipe line dredge (N)..... *58
electric ship completes trials, First British-built, Special London Correspondent *706
engine committee organized for Marine Congress (N) 575
engine developments in Great Britain, Special London Correspondent..... *164
engine electric ship propulsion, W. H. Wild 169
engine, Improved scavenging: Knudsen Motor Corporation *692
engine, Knudsen two cycle..... *618
engine, North British 2,000 horsepower double acting, Special London Correspondent *763
engined combination lighter and towboat ordered 70
engined tug displaces steam craft..... *30
engines at the marine show (E)..... 584
engines designed for large liners, Our Special London Correspondent..... *363
engines, Europe develops new types of, Special London Correspondent..... *599
engines must be developed, Lighter and cheaper, J. F. Nichols..... 677
oil motors for French fishing fleet (N)..... 645
propelled vessels, Possibilities of (N)..... 381
yacht Hussar, Auxiliary..... *341
Direction finder and sounding apparatus for small boats, Submarine: Submarine Signal Corporation *693
indicator, Plant mills: Bethlehem Shipbuilding Corporation *738
Directory of exhibiting companies at Marine Exposition 685
- Displacement, Measurements for "full" (Q) stability, etc. Methods preferable for calculating (Q) 310
Does an annual saving of \$40,000 interest you? L. B. Chapman..... *197
Does it pay to have a satisfied crew? J. F. Milliken *349
Donavin, K. H.: The Diesel and the future (L) 638
Don't give up the ships (E)..... 65
Doric, Propelling machinery of passenger steamship 216
Douglas fir in British warships (P)..... 503
Dredge, Control station for: Westinghouse Electric & Manufacturing Company..... *738
Diesel electric (N)..... *58
Dredges, Army launches first all-electric..... 763
Drill for plates, Multiple: Niles-Bement-Pond Company *118
Drydock, A new (P)..... 441
at Baltimore, New railway..... *163
designed for Mexico, Floating (N)..... 791
floating, carries 13,000-ton vessel on short voyage *95
floating, Largest in the world ordered... in Tampico, New (N)..... *37
opened in Canada, World's largest (N)..... 715
Dry docking facilities, Philadelphia lacks (N) 315
Du Brice Marine Motors: Motor for small boat propulsion *308
Duiello, New Italian Steamship (P)..... 230
Dumana, British motor passenger liner, London Correspondent *305
Duties of a marine superintendent..... 182
Dyson's method applied to merchant ship propellers, E. A. Stevens, Jr..... 507
225
- E**
- Eagle-Picher Lead Co.: Notes on sublimed blue lead 170
East versus west on the shipping question, C. A. McAllister..... 68
Eastern Company's new program (N)..... 380
Steamship Company of Canada, Ten ships for (N) 123
Steamship Line, Passenger steamers for *156
Easton, W. H.: Electric ferryboat Poughkeepsie *159
Economic operation of ships: Does it pay to have a satisfied crew? J. F. Milliken *349
Economical ship operation, Effect of the propeller on, E. A. Stevens, Jr..... *354
Economics of transatlantic liners of various lengths, C. E. Petersen..... 753, 759
of turbine electric propulsion, W. C. Watson and John Thomas..... *273
Economies, Engine room and shore: A direct course is a direct saving, R. B. Lea *361
Modern boiler room, J. J. Nelis..... 271
practiced by successful British shipowners, Our British Correspondent..... 351
Economizer that requires no outlay, An..... 356
Economy and efficiency (E)..... 253
in fuel consumption on Government ships (E) 453
in ship repairs, R. W. Morrell..... *343
in Shipping Board vessels, Fuel, R. D. Gatewood 22
in steamship operation and management, R. F. Hand..... 261
of motorships, Influence of speed on, L. B. Chapman..... 435
of steamships and motorships, Relative, L. B. Chapman..... 38
Oil burning affords great opportunity for, J. S. Milne..... 286
Editor of Marine Engineering and Shipping Age, New..... *519
Edwards Company, Inc., O. M.: Improved sash balance 742
Effect of joggling frames (Q)..... 709
of stevedoring costs on operating expenses, L. B. Chapman..... 71
of the propeller on economical ship operation, E. A. Stevens, Jr..... *354
Efficient repair methods adopted by Shipping Board, R. D. Gatewood..... 347
ships are those best meeting requirements, J. L. Bates 474
Efficiency and economy in traffic work, H. Sheridan *525
depends on accurate performance records, C. J. Jefferson..... *267
designing the marine power plant for, W. B. Flanders..... *292
in operation of oil tankers, Notes on, T. J. Smith *477
in the operation of steamships, D. A. J. Sullivan 19
of surface propellers (Q) 442
of the boiler, Influence of ash in coal on (Q) 784
Electric and geared turbine drive, W. C. Watson and John Thomas..... 557
auxiliaries an economic necessity, Walter Thau *276
bake ovens for marine use, Westinghouse Company develops..... *619

Electric—Continued

- contract for Diesel barges (N)..... 189
dredges, Army launches first all..... 763
drive versus geared drive. Analysis of
claims of the J. C. Shaw..... *417
ferryboat Poughkeepsie..... *159
motorship Twin Ports, First Diesel (N)..
propelling machinery of H. I. J. M. S.
Kamoi. W. L. Wright..... *25
propulsion, Economics of turbine. W.
C. Watson and John Thomas..... *273
radiator: Walter Kidde & Company..... *693
ship completes trials, First British-built.
Special London Correspondent..... *706
ship propulsion, Diesel. W. H. Wild.. 169
submerged log: Electric Submerged Log
Company..... *170
propelled 21-knot battleship Colorado... *605
Elizabethville, Belgian passenger steamship.

WE GUARANTEE that of this issue, 5,000 copies were printed; that of these copies 3,631 were mailed to regular paid subscribers, 311 were provided for counter and news company sales, 195 were mailed to advertisers, 81 were mailed to employees and correspondents and 782 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 5,000—an average of 5,000 copies a month.

MARINE ENGINEERING AND SHIPPING AGE is a member of the Associated Business Papers, Inc. (A. B. P.), National Association of Periodical Publishers, Inc., New York Business Publishers' Association and the Audit Bureau of Circulation (A. B. C.).

Requests for change of address should reach us two weeks before the date of the issue with which it is to go into effect. It is difficult, and often impossible, to supply back numbers to replace those undelivered through failure to send advance notice. In sending us change of address, please be sure to send us your old address as well as the new one.

Give the Standardization Committee Active Support

THE matter of the elimination of waste through simplified practice in shipbuilding and ship operating took very definite form at the meeting of the Standardization Committee at the Department of Commerce, Washington, on December 20. Had that committee existed prior to the war there is no doubt but what many millions of dollars would have been saved and many errors of judgment avoided during that trying period; while the chaos following the sudden termination of hostilities would not have been nearly as great as it was—and is. What would have been the outcome in the railway field after the frightful demoralization which resulted from government operation had that industry not started to clean house in the matter of variations in building and operating practices years ago and kept at it ever since? Then there is the more recent parallel in the automotive industry where the results have been marked. Again, right in our own field we have but to point to Great Britain, where the work of standardization began soon after the end of the war and is now proceeding deliberately and with well defined results.

But, "it is never too late to mend." The way is clear and the necessary machinery is almost ready, in the form of one of the ablest committees ever gotten together in the marine or any other field for any purpose. All that is now needed

is support—not passive, but active and hearty; and we have enough faith in the men from whom that support must ultimately come to predict that they will not be found wanting when called upon.

Labor Depends Upon Transportation

THE greatest blessing that any country can enjoy is steady employment at good wages for each and every one of its workers. This condition cannot be obtained in any nation unless its arteries of transportation are capable of handling the products of its farms and its factories expeditiously. Probably Henry Ford is prouder of the fact that he is giving steady employment to 100,000 men than of any other thing that he has accomplished. But Mr. Ford cannot continue to keep these men busy unless he can transport his automobiles not only to every place in this country but also to practically every port in the world.

It was stated and acknowledged on the floor of the Senate during the month just passed that 10,000 carloads of apples of the kind that we are paying ten cents a piece for here in New York city were dumped into the Columbia river from one section of the state of Washington alone. Neither sufficient warehouse space nor railroad cars for their transportation were available, but, if vessels equipped with refrigeration space could have been chartered at Seattle or Portland, the greater portion of this and similar crops could have been salvaged. And every shipload would have meant a payroll for the farmers and, through their increased purchasing power, employment for the workers of that section of the country.

Our statesmen have at last begun to realize that the influence of America is necessary to get Europe out of its economic chaos. Until it is made possible for the countries "over there" to resume normal production, the peace of the world is in danger. Even England has had, and still has, a serious unemployment question on her hands.

We have much to be thankful for at present. The indications, due to the immigration law, are that there will be plenty of work for everybody during the coming year, but this condition will not prevail, if either our rail or water transportation facilities are unable to handle the products of our industries. The ships of European maritime countries may at any time be withdrawn. Why then should we allow ourselves to depend on them?

Does not the Senate realize that the benefits to be derived from a merchant marine are general and not local? Does it not realize that the competition of an adequate American

merchant marine will insure reasonable transportation rates? Does it not realize that capital will not be interested in shipping unless the pending legislation is enacted into law, or must it wait until a catastrophe actually occurs?

Chamber of Commerce of the United States Urges Senate to Grant Government Aid to Shipping

ELLIOT H. GOODWIN, resident vice president of the Chamber of Commerce of the United States, has recently sent a letter to the members of the Senate urging favorable consideration of the ship subsidy bill. A communication of this kind, coming from such an institution whose special committees are constantly reviewing world conditions and their relation to our commercial prestige and national safety, ought to make a profound impression on any fair minded senator.

"In 1915," said Mr. Goodwin, "our membership, by a vote of nearly 3 to 1 favored subsidies from the Government, sufficient to offset the difference in cost between the operation of vessels under the American flag and the operation in the same deep sea trades under foreign flags.

"In March, 1920, in a new referendum the National Chamber's membership by a vote of over 15 to 1, coming from 44 states, the District of Columbia and American Chambers of Commerce, in Hawaii, Porto Rico, Alaska, Mexico, Italy, France and Cuba, favored a general declaration by Congress to give aid toward the maintenance of a privately owned and operated American merchant marine.

"Again in 1922 the subject was brought before our membership. At our annual meeting a resolution was unanimously adopted favoring an adequate privately owned and operated merchant marine, with aid from the Government which is essential to the maintenance of such a merchant marine.

"It was recognized then that our position as the second maritime nation of the world *newly gained as a result of shipbuilding operations during the war* could not be maintained without the grant of Government aid to present and prospective owners of our ships."

This newly gained commerce which Mr. Goodwin refers to as being a result of our shipbuilding activities during the war is strikingly illustrated in a recent report of the National City Bank of New York. This report says that the total exports for October, 1922, exceed any month in the past one and a half years. "They total \$372,000,000 and are not only the biggest of any one in the last 18 months but are nearly 20 percent above those of the immediately preceding month, 33 percent greater than in the opening month of the calendar year and 35 percent more than in the corresponding month of the preceding year."

An interesting feature of the increase in our export trade is the fact that the principal gains have been made by the manufacturers and exporters who are endeavoring to hold on to the business that they gained in the World War.

Comparing our export returns for the month of October with those of Great Britain, we find that our chief maritime rival suffered a loss of \$10,000,000 in her exports as com-

pared with the month of September. British domestic exports for October totaled \$294,000,000 as compared with about \$366,000,000 of domestic exports from the United States in the same month.

From a report just received from the Department of Commerce a new high record for the year was established for November, which shows that American industries benefited from the export business during that month to the amount of \$383,000,000. Comparing November, 1922, with the same period of 1913, an increase of more than \$138,000,000 over pre-war shipments abroad is shown.

Remembering that the United States is now clearly the leading nation in domestic exports whereas in 1913 Great Britain exceeded our domestic exports by over \$100,000,000, can anyone having ordinary common sense fail to see the important role that has been played by American ships even under Government ownership and the vital factor that they are bound to become to the future prosperity of the whole nation?

"Der Tag"

MR. McCAY'S splendid cartoon which appears on this page indicates the present status and the future of the American merchant marine in a far clearer way than it can be expressed by language. Many of us have waited through long dreary years for "der Tag" when America would resume, as of yore, her rightful place on the seas and in the ports of the world.

Time and time again our hopes have been raised that our people at last realized the vital necessity of an adequate merchant marine only to have them shattered through a lack of understanding and the sinister influence of foreign shipping interests. Some Americans seem to have a mania for

Copyright, 1922, by Star Company

Coming Out of the Fog

—McCay in the *New York American*

doing and saying things that will please our foreign maritime competitors and even certain daily newspapers in this great seaport of New York whose very existence depends upon American patronage have taken every opportunity to misrepresent every constructive effort that has been made to build up an American merchant marine.

How the American people, having the knowledge that the lack of an adequate merchant marine compelled this country to spend between three and four times its pre-war national debt for the construction of emergency ships, have allowed constructive action to be delayed thus far is beyond our comprehension and the only answer seems to be that it has been due to powerful forces working behind the scenes.

At last, however, and largely through the influence of President Warren G. Harding, the House of Representatives has, for the first time in our history, passed a general subsidy bill. We know how it is with the President and at this writing the Senate alone stands in the way of the fulfillment of the country's destiny. Business men naturally discount any deal that is not signed, sealed and delivered, but in this case we believe that Mr. McCay has accurately portrayed the future, because the opposing senators have only temporary or permanent Government ownership of shipping to offer as an alternative, which means that their position is too weak to prevent a 'show-down' before March 4.

The Motorship Outlook

IT has been the general belief that until the great surplus of cargo steamers owned by the Government could be sold to private owners and absorbed in the trade, shipyards could hardly expect much in the way of new construction except in passenger liners and special types of vessels. Admiral Benson, however, is showing the way not only to dispose of a number of these vessels but also to give the shipyards and repair yards a great deal of work in converting them into motorships at a cost upon which the fixed charges as compared with a steamer will not eat up the great fuel savings of the Diesel engine.

Admiral Benson is holding conferences with representatives of the shipyards and manufacturers of Diesel engines and equipment in order to determine the proper differential that the Shipping Board ought to place upon the steamers that it sells, as is and where is, and the vessels that it disposes of on condition that they are converted into motorships. In addition to this, the conferences are intended to bring out any points or ideas that will indicate how the total cost of the entire motorship machinery installation may be reduced to a minimum.

As the vessels owned by the Government may be classed in a very small number of types, the problem is entirely different from that of constructing new ships of varying characteristics. For instance, the question was brought up, cannot the sizes of the deck and auxiliary machinery for each class of vessels be standardized as to sizes?

It is plain that if such a work could be done by an authoritative committee—and considering the data that the Shipping Board must have on hand relating to the past performance of these vessels, it ought not to be so difficult a

job—immediate dividends would be realized in obviating the necessity for the cost of new plans and specifications by each purchaser.

Again, where fixed units are determined upon, it would enable the electric companies to reduce the cost of producing motors for the same to a minimum. In fact, would the matter not be reduced to a stock proposition?

While it is not our policy to at any time advocate machines of any particular manufacture, nevertheless we do think that by reducing the number of sizes and powers required concentration of effort will the more quickly produce units of maximum efficiency.

At the present time it may seem a bit facetious to suggest anything that savors of quantity production, but the fact should not be overlooked that the Shipping Board is prepared through concessions on its surplus stock of existing vessels to make it possible to obtain motorships in this country cheaper than they can be built anywhere in the world.

Tramp Contracts Signify Revival in English Shipbuilding

IN England those in close touch with the shipbuilding industry have said that the first sign of a genuine revival in the trade would be the ordering of a fair number of tramp steamers. Quite a number of contracts for ordinary cargo steamers of the tramp type have been placed in the United Kingdom during the last six weeks, so if indications that have heralded returning activity in shipbuilding in former times hold good a change for the better is in sight.

One of the most significant reasons why England has made such a great success as a maritime nation is the fact that British shipowners have always pursued the policy of disposing of their out-of-date vessels to foreigners. Although action of this sort has been prevented during the present depression by a lack of market abroad, it is fairly safe to prophesy that the next few years will witness a transformation in the British merchant marine in which post war designs of the most efficient type will prevail.

It should be recognized that the lack of the most up-to-date and efficient types of vessels is a far greater handicap to the success of any merchant marine than any wage or manning differentials now existing. England's maritime success proves this, for her wage costs are much higher, with the exception of the United States, than her competitors.

Just as surely as the iron ship and the screw propeller drove the wooden sailing vessel off the seas so will the most efficient vessels of the future which are capable of giving the greatest returns for the money invested make it impossible for a large percentage of the so-called surplus world tonnage to operate. And, further, when that time comes it will be found that new ships cannot be constructed as cheaply as they can be now. The new English contracts would not have been forthcoming if the bottom in prices had not been reached. America will profit by accelerating rather than retarding the tentative construction, reconditioning and conversion projects now in hand.

Sufficient Votes to Pass Subsidy Bill Are Assured; Night Sessions Will be Resorted to if Necessary

Senator Jones in Brilliant Address Tells in Plain Language Exactly What the Provisions of Bill in Present Form Are

THE Merchant Marine Bill with amendments to the House bill as proposed by the Committee on Commerce was reported to the Senate on December 9. The majority report favorably recommending a decision on the measure was signed by 11 members of the committee, and the minority report presented by Senator Fletcher was signed by 5 members of the committee.

At this writing fully 48 senators are committed to vote for the bill and only one of the doubtful class is necessary to assure its passage. Of course the principal anxiety of the proponents of the measure is the possibility that the opposition may succeed in delaying action until March 4. In order to prevent such a catastrophe to the welfare of our shipping, Senator Jones has determined to have the Senate convene at 11 o'clock instead of 12, wherever possible, to keep it in session until 5:30 or 6 every evening, and to insist on night sessions if it is found to be necessary. Friends of the measure will also be asked to attend all sessions regularly to prevent delays incident to roll calls where the point is made of no quorum.

NORRIS BILL CANNOT SUPPLANT SHIPPING ACT

Senator Norris has had a bill reported to the Senate which provides for a revolving fund of \$100,000,000 for the purpose of buying and selling farm products. It is not believed, however, that this bill, which is not the rural credits legislation sponsored by the Administration, can secure enough backing to block the shipping bill.

The rural credits measure is expected to be whipped into shape for presentation to the Senate during the first part of January, and then the shipping act will probably be temporarily sidetracked for the farmers' bill. The farmers' bill, however, will not take much time, as there is little opposition to giving all reasonable assistance to agriculture. After the Senate has assisted farming, it cannot consistently refuse similar aid to shipping.

SUBSTANTIAL CHANGES MADE

A few substantial changes have been made in the shipping bill as passed by the House by the Committee on Commerce. There are also a number of minor changes.

The taxation exemptions concerning the operation and sale of ships were stricken out. They are already in the Jones Act of 1920.

The amount of compensation that may be paid in any one year is limited to \$30,000,000, which is considered sufficient to provide for an American merchant marine carrying over 50 percent of our commerce.

The provision in the House bill requiring specific appropriations to be made annually from the merchant marine fund has been stricken from the bill. In its place it is proposed to forbid the Shipping Board from increasing compensation provided in any contract without a specific appropriation from Congress. It was believed that the provision of an annual appropriation even from an existing fund would prevent capital from investing in shipping ventures, although there is little doubt that Congress would live up to all legitimate contracts. In connection with this we might say that Congress has the power to repeal the Shipping Act at any time, even at the next session if it so desires,

but that it would not invalidate any contracts made up to the time of the repeal.

It is also provided that no contracts shall extend beyond 15 years from the enactment of the law. If at the end of that time we have not built up a merchant marine, it will be necessary to devise another plan.

SENATOR JONES' SPEECH

Senator Jones made a brilliant speech on December 12 and 13, which was a masterpiece for plain reasoning and plain language. While he attributed to the opponents of the shipping bill all the sincerity of purpose that actuates those who champion it, nevertheless, it is beyond our understanding how anyone having the privilege of hearing Senator Jones' address and at the same time knowing how the lack of a constructive shipping policy has kept American privately-owned ships out of the foreign trade for 60 years, can honestly and conscientiously oppose the present measure.

The following analysis of the shipping bill in its present form was included in Senator Jones' address, and to our mind it is the best explanation of the measure so far given, for it tells in language that everyone can understand just what this highly technical and complex act provides.

TITLE 1—AMENDMENTS TO JONES ACT—SALES

The amendment broadens the power of the board to make sales, but limits the minimum rate of interest to $4\frac{1}{4}$ percent, the maximum period of time over which payments are to be distributed to 15 years, and provides that the payments must at all times cover the depreciation of the vessel. The *Leviathan* may not be sold for less than the cost of reconditioning.

That is one provision put in in the House. There probably will be considerable discussion about that. It is going to cost about \$9,000,000 to recondition the *Leviathan*. Her sister ships were reconditioned by the British Government and turned over to the British companies for \$4,000,000. How we can hope anybody would take the *Leviathan* and pay the \$9,000,000 for her and then compete with these sister ships I do not know, but the Senate committee did not see fit to strike out that provision.

The sales policy is also amended to emphasize the desirability of maintaining routes from outports and of giving the domestic communities primarily interested the first opportunity for two years to purchase such routes. Domestic communities are defined. The bill affirms the purpose of discouraging monopoly in shipping.

INSURANCE

Purchasers on the deferred-payment plan are required to keep the equity of the United States insured, protected by hull insurance, and, if the board so requires, by protection and indemnity insurance. The board may create an insurance fund in which it may insure any plant or materials owned by the board or the equity of the United States on any vessel or in which a purchaser may insure the equity of the United States if he is unable to insure such equity in the American insurance market at as low a price as it could be placed abroad.

CONSTRUCTION LOAN FUND

The act of 1920 is amended so that the construction loan fund of \$125,000,000 may be created as the money becomes available instead of at the rate of \$25,000,000 per year. The loan may be used for the construction of the most efficient types of vessels or the installing of efficient machinery in existing hulls.

The loan is limited to an amount of two-thirds of the value of the ship constructed or re-equipped, and may not be loaned for longer than 15 years nor at less than $4\frac{1}{4}$ percent interest.

The Senate committee reported a proviso prohibiting the loan of this money to companies or corporations for the building

of ships for the carrying of their own products. The committee thought it was wise to make that limitation on that fund.

MAIL

The act of 1920 is amended by withdrawing the power which it gave to the Postmaster General in conjunction with the chairman of the Shipping Board to make contracts for the carriage of ocean mails. The ocean mail act of 1891 is repealed.

TITLE 2—EXEMPTION FROM TAXATION

Title 2 of the bill concerns taxation, and there were two provisions in that as it passed the House providing for an exemption from income tax on the operation of the ships and on the sale of ships. Those were provisions which were in the act of 1920, and it was hoped that under the conditions existing at that time many new ships would be built under those provisions, but for some reason the Treasury Department rules and regulations authorized in that act have not yet been made and approved, and so those provisions have not been put into operation. It was stated by the experts that there would be no practical benefits from those provisions at this time under the present laws and in present conditions, and so the committee struck out those two provisions from the bill as it passed the House.

TONNAGE DUTIES

Tonnage taxes are doubled for all vessels of such size as to make them, if otherwise eligible, recipients of direct aid.

TITLE 3—CONCERNS IMMIGRATION

This title declares the policy of the United States to be that one-half of our immigrants shall be carried in American bottoms. The President is directed to take such steps as may remove treaty stipulations conflicting with this policy. When no conflict exists, the policy is to be carried out under regulations approved by the Secretary of Labor and Secretary of State.

TITLE 4—CONCERNS DIRECT AID

MERCHANT MARINE FUND

A merchant marine fund is created from all tonnage taxes, 10 percent of all customs duties, and the direct aid refunded by owners who have made 10 percent profit or more in any one year.

THE CONTRACT

Section 403 authorizes the Shipping Board to enter into contracts for the payment of compensation. The contracts may run for 10 years and compensation shall be paid at reasonable intervals, not exceeding six months. The board may refuse for good reasons to enter into a contract on a vote of not less than five members.

The committee put in a proviso to that amendment relating to contracts, expressly providing that no contract shall extend beyond a period of 15 years from the enactment of this act. It was pointed out that under the language of the bill a contract might be made for 9½ years, and then renewed for 10 years, so that a contract might run for nearly 20 years. The committee inserted a proviso stating that no contract shall extend beyond the period of 15 years from the enactment of this act, which cuts out that possibility.

DETERMINATION OF AMOUNT OF COMPENSATION

The amount of compensation is based upon the distance steamed and the rate allowed per hundred nautical miles. The rate depends upon the size of the vessel and the speed of which she is capable, in the case of power-driven vessels, and upon the size alone in the case of sailing craft. Mileage is based upon chart distance between ports, except that a different distance may be allowed in special cases if the board deems it necessary.

The following requirements must be met by the vessels:

She must be maintained in the highest classification in the American Bureau of Shipping.

Two-thirds of her unlicensed crew must, after three years, be composed of American citizens, and the remainder must be eligible for citizenship. In the case of passenger vessels this does not extend to the steward's department.

She must be self-propelled over the mileage covered, except in cases of distress or in navigating harbors or inland waterways.

She must be built in the United States, except that certain vessels built before the enactment of the act may be admitted to compensation if registered under the American flag within three years and if five members of the board so vote.

She must be engaged in foreign trade as defined by the bill.

Certain feeder ships primarily serving the foreign trade of the United States are also eligible.

Three-fourths of the total fleet, owned, operated, or chartered by an owner receiving compensation, must be American.

VARIANCE OF RATE

The board may vary the rate of compensation set by the bill within limits of 100 percent either way upon a vote of not less

than five members of the board. According to the amendment recommended by the Committee on Commerce this will have to receive the sanction of Congress.

OBLIGATIONS OF COMPENSATED OWNER

An owner receiving compensation agrees that his vessels may be requisitioned in time of emergency upon a fair pre-emergency value. Sale of the vessel carries this obligation with it to the new owner. All repairs and renewals, other than distress repairs, are to be made in American ports.

The owner contracts to repay to the Treasury half of the amount by which in any one year his net income exceeds 10 percent on his invested capital until the amount of aid received by him in that year shall have been refunded. Detailed provisions are included for the administration of this section.

That, briefly, explaining it a little more, means this: Of course, it is not desirable, and it ought not to be the case, that compensation would be given to a vessel owner who is making a large profit in the operation of the ship. The committee does not desire that to be done. So we have provided that where the profit of the ship operator exceeds 10 percent in any year one-half of the excess comes back into the Treasury of the United States up to the amount of the compensation that may be paid.

TITLE 5—PERTAINS TO THE ARMY AND NAVY TRANSPORT SERVICE

Section 501 provides that where adequate commercial transportation exists military services may be discontinued by the President. The military departments are authorized to contract up to 10 years with commercial organizations for such services.

TITLE 6—PERTAINS TO RAIL AND WATER TRAFFIC

CREATION OF THE JOINT BOARD

The creation of a joint board from the Interstate Commerce Commission and the Shipping Board is authorized. Such board is to make recommendations looking to the correlation of rail and water traffic.

I will say for myself that I feel that that is one of the most important provisions in the bill. I feel that if we are going to have a merchant marine upon a permanent basis, even with the aid here given, we must co-ordinate and bring into close co-operation the railroad water lines of the country.

EXPORT BILLS OF LADING

The Shipping Board is to authorize the form of bills of lading for the water-borne portion of a through shipment of goods where the Interstate Commerce Commission establishes the form for that portion of the shipment over American railroads.

RAIL-OWNED WATER LINES

This section amends paragraph 9 of section 5 of the Interstate Commerce Commission act to the end that railroads may own steamship lines where the latter do not come into possible competition with any rail lines.

AGREEMENTS BETWEEN CARRIERS

Section 605 amends the shipping act of 1916 so as to amplify the power of the board to investigate agreements between common carriers or between common carriers and terminals.

JOINT OR PROPORTIONAL RATES

Section 607 amends section 28 of the merchant marine act by making it mandatory on the Interstate Commerce Commission to invoke or suspend section 28 as the Shipping Board certifies adequate or inadequate American transportation is available. Where the board and the commission are of the opinion that section 28 will cause congestion or will deflect unduly the natural channels of trade, the section shall be suspended.

TITLE 7—COMPRISES MISCELLANEOUS DIVISIONS

OFFICIAL TRANSPORTATION

Section 701 provides that the transportation of passengers and commodities paid for by the United States Government shall so far as practical be in American bottoms.

REPORT BY THE SHIPPING BOARD

The shipping act of 1916 is amended to include in the required annual report a complete report of the board's transactions with regard to the merchant-marine fund and the construction-loan fund.

One of the principal objections I have seen urged to the bill has been the failure to require the board to make these reports, but that provision was put in on the floor of the House, I think, and came over as a part of the House bill requiring them to submit the report.

HOME PORTS OF UNITED STATES VESSELS

The Secretary of Commerce is authorized to designate the port of documentation of American vessels, and such ports shall be

the ports where the greater part of the vessels' business is conducted.

SURRENDERED DOCUMENTS

The shipping act of 1916 is amended so that documents can not be surrendered in time of peace without the approval of the board.

REGULATIONS

Section 703 authorizes the Shipping Board to make the necessary regulations to carry out the provisions of the act.

Hurricane Proves Reliability of Motorship

IN the recent hurricane that swept the North Atlantic, against which even the giant liner *Majestic* could only make 5 knots, the single screw motorship *Munmotor* of the Munson Steamship Company gave a splendid demonstration of the reliability of the Diesel engine. The *Munmotor* is one of the Lake type vessels having fuller lines than are considered satisfactory for the Atlantic service. She has a length of 253 feet and a beam of 43 feet 6 inches and is propelled by a McIntosh and Seymour 4-cycle Diesel engine of 900 brake horsepower.

Although a complete report of the voyage has not been received at this writing at the Munson Steamship offices, it is understood that heavy seas broke over the forward deck damaging the cargo hatch and admitting enough water to shift the cargo and give the vessel a decided list. It should be noted here that the vessel was fully loaded with 4,000 tons of bulk coal at the time but that, in spite of the damaged condition, she was able to ride out the storm safely and then proceed to her port of destination.

A thorough examination of the engine since the storm has shown the machinery to be in excellent condition, and the only damage found was where the straining of the ship had loosened a few joints in the pipe lines. The performance is all the more noteworthy due to the fact that the ship is fitted with a single screw installation depending solely upon one engine.

(Photograph by Kadel & Herbert, N. Y.)

Sea Wall Made from Scrapped War Vessels

A new use has been found for obsolete warships; instead of being broken up, they are towed into place, filled with stone and made a part of a sea wall. The illustration shows a one time "Jed" being worked into a sea wall at Dartmouth, Eng.

Wrecked Tanker Lyman Stewart on the Rocks North of Cliff House, Golden Gate

Following a head-on collision in the north channel of the Golden Gate at the entrance to San Francisco Bay during a dense fog recently with the Luckenbach steamer *Walter A. Luckenbach*, the Union Oil Company tanker *Lyman Stewart*, outbound to Seattle with 65,000 gallons of crude oil, was abandoned on the jagged rocks just north of the Cliff House, where, with a deep hole torn in her port side, she had been swept by the heavy ebb tide. The *Lyman Stewart* is of 5,919 net tons, built in 1914 at the Union Iron Works, San Francisco, Cal.

Sidelights on the Shipping Bill

By "Old Scotch"

"Well begun is half done" is an old adage, applicable to many undertakings in life and particularly so to the shipping bill now in the process of transformation into the law of the land. To one who attended the sessions of its turbulent passage through the House of Representatives there are a number of interesting sidelights not covered in the press reports, some of which are outlined in this article.

THE outstanding impression one gained from the onslaughts of the opponents of the ship subsidy bill is their absolute selfishness and unfairness to the maritime interests of the country.

The term "subsidy," wished on the measure by its opponents, was anathematized to a fare-ye-well. In itself the term means nothing of the sinister definition applied to it. The word "tariff" means just the same thing, so far as the effect is concerned.

HYPOCRISY OF THE OPPONENTS

Much of the bitter invectives hurled at the shipping bill came from members in the West and Northwest, who but a few weeks ago were imploring the House to place duties upon agricultural and other products of their particular districts. The opponents from the South, who were the most active in their denunciation of this alleged "raid upon the Treasury," are always in the front rows begging for large appropriations for "good roads," "rural free delivery," "boll weevil cures," "pellagra funds" and what not, because, forsooth, they were beneficial to their particular districts. Has anyone ever heard of the representatives of districts interested in shipbuilding and ship operation ever opposing measures of that kind, even though their districts received no particular benefits from such legislation?

Millions of dollars have been spent for reclamation of arid lands, to benefit the agricultural interests of the great West. Is not that a subsidy? and a beneficial one at that? The maritime interests have always lent their aid to all of these meritorious projects, else they never could have become laws.

AID FREELY GRANTED FOR BUILDING RAILROADS

If we want to confine this argument to means of transportation, which is all that the shipping bill calls for in fact, let us but harken back to the days a half century or so ago, when the great transcontinental railroads were built. Private capital could not be enlisted in these great undertakings, because they would not pay attractive or, in fact, any interest rates. But the great object to be accomplished was so transcending that our representatives then in Congress, and real statesmen, too, granted vast acreages of the public domain and guaranteed the bonds necessary for the construction of these roads. Has the Government ever made a better disposition of its lands and its credit? Is there any marked difference between starting these lines of communication on the land, than there is in this proposed establishment of lines on the seas? A nation's shipping is but the continuance of its rail facilities on land.

The great middle states of Ohio, Indiana and Illinois supported the measure valiantly, and their representatives in the House made some of the best speeches in its favor. Can their interests be any different than those of the representatives of Iowa, Minnesota and Wisconsin? As a body they are apparently as intelligent. Their opposition must therefore be attributed to innate selfishness, for those particular states have been the most insistent for high tariffs on their wheat and other products of the soil. The consumers of the greatest portion of their crops are located in the great centers

of population along the Eastern seaboard. We who live here and wrest a livelihood from the business of sea transportation do not care particularly to have the price of our daily bread greatly increased by the tariff in order that the farmers of Iowa and Minnesota may make a living wage from raising wheat and corn, but we realize that our agricultural interests must be made remunerative in order that the country may be prosperous, and we accept the conditions placed upon us by Congress cheerfully.

We who build and operate ships have as much right to have our occupations protected as have the farmers. You cannot place a protective tariff on ships sailing the Seven Seas in open competition with all the world, so our only means of protection is for the Government to help us make up the difference in labor costs between the American standard and the standards of our low cost labor competitors on the ocean.

SELFISH ATTITUDE OF AGRICULTURAL REPRESENTATIVES

Do the representatives of the farmer districts realize that, if this shipping bill, or something equal to it, is not passed and very soon, it will mean the closing of over 75 percent of all the shipyards in this country, and the throwing out of employment of thousands of men? Have they forgotten that the disarmament program, which eventually must benefit the whole world, has already thrown out of employment not less than 25,000 men who were and have been from youth employed in shipbuilding? Are these men and their families alone to bear the brunt of a policy which benefits all other of the great industries in the country? Must one industry such as this be annihilated and the honest men, who have heretofore gained their livelihood in shipbuilding, be thrown out on the streets, because of a spirit of selfishness and unfairness on the part of certain of our agricultural representatives in Congress who would take away their last chance of employment by denying the shipping interests that which is their just due?

Most of us have been taught that the American farmer is our highest type of citizen, both in patriotism and intelligence, the very backbone of our citizenry. We still believe it, but if their elected representatives, who frothed at the mouth at the very mention of a measure to help the shipping industry, reflect the sentiments of their constituents, it must be because of an absolute lack of knowledge of the actual conditions. If every farmer in the United States has carefully read President Harding's recent message on the shipping situation, there ought to be some new faces in Congress from certain Western districts two years hence, and undoubtedly there will be.

SHIPPING AS A MEANS OF NATIONAL DEFENSE

Another outstanding feature of the six days' debate was the subordination of that phase of the shipping situation, connected with our national defense. The commercial side is of great importance naturally, but the preparedness side of the issue should have been given greater prominence than it received. The clause regarding payments to the so-called "Industrial" ships was unceremoniously stricken from the bill, because the names of Standard Oil and United States Steel Corporation were included among the beneficiaries. Of

course it would take a pretty brave Congressman to explain to his constituents that he had voted to pay money to either of these great, wealthy concerns for carrying on their own business. From the strictly commercial side of the bill it must be admitted that the average citizen would require a lot of demonstration to believe it advisable. Not, however, if he would view it from the broad standpoint, that the money for operating these ships could be kept at home by the small payments authorized in the bill. In domestic trade a few cents added to the cost of gasoline would soon make up any differential in operating costs. But when these great oil companies go into the foreign trade, they must meet very keen competition.

TANKERS ESSENTIAL IN WARFARE

It is from a standpoint of national defense that this great fleet of tankers should be considered. If Government help is not extended to those operating in foreign trade, it is a foregone conclusion that they will either be tied up and soon deteriorate, or else they will be transferred to foreign flags, where most of them were before the outbreak of the great war. No type of merchant ship is more valuable to the Government than tankers, in time of war. Whether hostilities are conducted on the surface of the ocean, underseas, or in the air, vast quantities of fuel oil and gasoline will be required, and will be as indispensable as explosives. Without a large fleet of tankers ready at a moment's notice, we would be helpless to conduct any kind of war, even though the scene of action was within our own borders.

At a certain stage of our own part in the last war, such oil carriers would have been worth \$10,000,000 each, as it will be remembered that our fleet was very small at the outset of our entry into the war, and several of the largest tankers were sunk by submarines. There seems to be but little chance of having the "Industrial" fleet compensation put back into the bill in the Senate. Hence the prejudices of

certain of our misguided Solons, may eventuate some day in a national calamity.

LESSONS OF THE WAR MUST NOT BE FORGOTTEN

This only illustrates the general tenor of our lawmakers' attitude at this time. So far as many of them are concerned the late war might have happened fifty years ago instead of but five. So far as our dependability on merchant shipping is concerned the lessons of that great conflict have already been forgotten. The nearly four billions of dollars which were then feverishly invested in improvising a merchant fleet, to make up our delinquencies for the past fifty years, could have been mostly saved to the taxpayers, by the payment during that period of an average of \$5,000,000 annually in aid to our merchant shipping. Now and for many years to come the taxpayers of this country will be burdened with a tax of not less than \$150,000,000 annually, to pay the interest alone on that portion of our debt incurred in building ships. Who can tell how long it will take to pay off the principal? What a monument to Congressional short-sightedness! What a commentary on sectional selfishness and unfairness!

But there is still hope that we may overcome a repetition of such foolhardiness. The passage of the bill in the House by the comfortable majority of 24 votes marks the first time in history that the lower House has ever passed legislation of this kind. The thorough debate and the wide publicity given to the President's able message on the subject must have some good effect. In spite of the dire threats of certain elements in the Senate to defeat the measure, the American people certainly will not see this measure defeated. If the public will but think of the lessons of the past, and insist on their representatives in the Senate rising above selfish and provincial ideas, the bill will yet become a law, crippled although it may be. The bill is a constructive piece of legislation and should pass without delay.

Cunard Liner Tyrrenhia, Built and Engined by William Beardmore and Company, Ltd., Dalmuir, Glasgow, Scotland

This vessel is a twin screw, double reduction, geared turbine, oil burning steamer, 580 feet in length, 70 feet in breadth, of 17,000 tons gross, 13,500 shaft horsepower, and 17 knots service speed. She has accommodations for 265 first class, 370 second class and a large number of third class passengers. In common with all Cunard Line ships built since the close of the war, space is economized greatly by the adoption of geared turbine machinery and oil fuel, which allows power to be increased and calls for only one large funnel, thus leaving much valuable amidships space for the use of passengers.

Recent Developments in Marine Insurance

Instructions to Salvage Branches—Lightning Covered—War Risk Refunds—Ship Repairs Liability—Lake Cover Extended

By "Bordereaux"

FOLLOWING the final report of the cargo underwriting conferees to the Shipping Board authorities, extended allusion to which was made in this department last month, the United States Salvage Association has issued explicit instructions to all its branch offices outlining the service expected of them in order that the association may fully realize the hopes of the board and the underwriters in the matter of co-operative efforts to maintain a high standard in the condition of the board's vessels. By the terms of the report, it will be remembered, the responsibility was placed fairly upon the shoulders of the Salvage Association for seeing that the upkeep of the boats is maintained on a basis that warrants the continued granting of the "liner" and "approved steamer" ratings already arranged by the underwriters. Those ratings are to be conditional upon the maintenance of a standard of upkeep that meets with the approval of the Salvage Association. In its instructions to its branch offices the home office of the association insists upon the greatest care in considering the following factors:

(1) It must be seen that each vessel trading out of each branch's district does not put to sea in an overloaded condition. Cases of overloading must be promptly reported to the association's home office, to the agents of the locality, and to the Shipping Board authorities for action.

(2) Periodical surveys will serve as a medium for determining the physical condition in which these vessels are being maintained, but they must be followed up to ascertain if the recommendations of these surveys are carried out. The home office must be immediately notified of any failure to carry out the recommendations. These condition surveys should be made to cover in addition to the information called for therein any other feature of construction or operation which would materially detract from the vessel's cargo-worthiness or improve her standing in that respect. Such recommendations would cover such items as unprotected sanitary and scupper pipes, insufficient ventilation in cargo holds, the removal of steam and exhaust lines from cargo holds when such a step is advisable for the safe carriage of dry and perishable cargoes, unprotected steam pipes, unsheathed bulkheads on tanks carrying fuel oil, and other similar items. Such items as these must be brought to the particular attention of the operators, the local Shipping Board office, and also to the attention of the home office, together with the necessary recommendations for their correction. When urgency dictates, telegraphic information on such points is to be resorted to, in order that the least possible delay may be had.

(3) One of the original recommendations of the Cargo Conference Committee expressed approval of the desire of the Shipping Board to eliminate the shifting of personnel on its vessels, and particularly stressed the point that the chief engineers should follow their ships. It is therefore expected of the branch offices that whenever any of the designated ships are under their observation they shall acquaint themselves with the character of the personnel, particularly as respects the feature just mentioned.

The home office is to issue periodical bulletins which will advise the underwriters of the status of each of the vessels comprising these various fleets. It is therefore necessary that prompt information be forwarded with respect to any shortcomings in any of the vessels trading out of each branch's

district. The concluding language of the instructions is as follows: "We shall place upon your office the responsibility for the condition of any of these vessels leaving your district, and for the manner in which cargo is carried, in the sense that cargo damages resulting from defects in the condition of these vessels, which should have been eliminated before sailing, must be eliminated."

Lightning a Sea Peril

IN a recent opinion under an inland marine policy as to the liability of underwriters for loss by lightning doubt was expressed by a prominent admiralty lawyer as to whether the insurer could be held responsible, and the result has been to arouse so much uncertainty in the minds of brokers and the assured that frequent requests are being made to underwriters to include the word "lightning" in the perils clause of the policy.

The absence of decisions on the subject by the courts seems to have worried the lawyer, but the view of the underwriters is that the paucity of interpretation of the subject arises from the fact that lightning is a peril that would never be called into question by them. It is possible that the specific inclusion of lightning in fire policies has led to confusion in the minds of some, but it takes but little thought to appreciate that there is but the slightest analogy in scope between the perils clause of a marine policy and the single hazard of fire in a fire policy. Not only does the former specifically cover fire, but it includes loss or damage from all perils of the sea. The fortuitous nature of the happening is vital. It is, in the language of an authoritative court, "something which could not be foreseen as one of the necessary incidents of the adventure." This is, in point of fact, an excellent definition of lightning.

While it may be argued that it is not peculiar to the sea, it nevertheless remains that such a test is not applicable to sea perils, no more than winds would be. Nor can a parallel be drawn with rainwater damage, which is held not to be a peril of the sea; rain is a usual and necessary incident of the adventure, and damage from it can be foreseen and prevented with ordinary precaution, and that element of care enters into packing and handling of goods. In the judgment of most underwriters there is no question of the inclusion of lightning in the term "perils of the sea," constituting, as it most certainly does, a fortuitous happening.

Low Hull Rates

UNDERWRITING hulls is now going on briskly, with accounts being made up to attach January 1. Complaints are general, on both this side of the Atlantic and the other, of low valuations and the continuance of high repair costs. It is stated in England that the insured value of a modern tramp steamer of over 1,000 tons is based on about £8 to £10 per ton, and that risks have been placed on values as low as £6 per ton. Save in only exceptional instances the £15 and £20 valuations of a year ago are unheard of today. In the present condition of the shipbuilding industry there is believed to be no profit in such rates and values as now obtain. Underwriters rest their sole hopes

in possible reductions in repair costs, and this has been promised in England, if the proposed reduction in shipyard wages becomes an accomplished fact, and that appears certain now.

Would Reclaim War Risk Premiums

THE close of the year was signalized by a widespread movement among American importers and exporters to lay the foundation for a demand upon the German Government for the return of war risk premiums paid by the former during the period of 1914-1918, on the ground that this was an expenditure caused by the operations of German submarines and cargo-raiders. There are hundreds of millions of dollars of German funds sequestered in this country, and the idea was to press for recovery from this vast sum and to make use of the United States Government's special commission on redeemable war costs for the purpose. The time limit for presenting claims to this commission expired with the year, hence the importunities of numerous brokers during December for their underwriters to supply them with statements of their clients' war risk premium payments. This finally developed into the greatest sort of a nuisance to the insurance men, already overworked with the year-end special duties, and many offices made a charge for the extra work of 10 percent of the premiums, and some even added a \$20 bonus for good measure.

It is the practically unanimous opinion of the underwriters that this movement is a great mistake, that it is wrong in principle, unjustifiable, and with next to no likelihood of resulting successfully. They insist that the war risk premiums were, at the time, passed along to the consumers, and that the insured therefore have never been out of pocket because of them. Furthermore, the underwriters fear that, if such claims were allowed, it would greatly prejudice the subrogation rights of the insurance companies. They feel there could be no effective reply to the possible objection of the German Government that as the assured had already received back their war risk premiums there was nothing due the underwriters, in view of the fact that they had accepted the risk at a rate acceptable at the time and so must have felt themselves properly reimbursed for the hazards involved. As a matter of fact, the second half of this argument is so strong that many underwriters seriously question the wisdom of they themselves undertaking to lodge claims for war risk losses against Germany. The whole subject is as applicable to the insurance interests of ship owners and ship operators as to those of the merchants who have been making such an ado over it.

Lake Cover Extensions

NAVIGATION on the Great Lakes closed on December 12, but by special arrangement insurance coverage was extended somewhat beyond that date this season. The move originated in London where additional periods of coverage were allowed to certain Canadian fleets in consideration of an extra premium of one-half of one percent. American underwriters felt that this was an unfair advantage to the Canadians, and a special committee of the American lake underwriters decided to make a like charge for an additional period of three days, from midnight of December 12 to midnight of December 15, with the intimation that a further extension might be made if it should appear desirable. But they later decided to go no further than the 15th, and it is probable that the attitude of the Great Lakes Protective Association had a great deal to do with this determination. The Advisory Committee of the latter body held a special meeting on the subject and unanimously disapproved of any extension whatever; however, they reluctantly concluded to "follow the regular underwriters up to midnight of December 15th," but positively refused to go beyond that date.

The Association represents about three-quarters of the cargo tonnage of the Great Lakes, and they carry 25 percent of their own insurance. The more conservative members always lay up their vessels after December 12, and that element naturally was averse to taking chances for the benefit of the more reckless minority. When their decision was made known to the underwriters all talk of further unrestricted sailings ceased forthwith. It might be added that there is always a dangerous come-back to chance-taking with post-season storms. Last year underwriters felt jubilant over their lake experience in mid-December, only to see most of their profit melt away under the influence of subsequent reverses. Thus this year, after a fairly successful season, tremendous drain on the profits was had in consequence of heavy lighter losses sustained in the period of two weeks.

Refund of Ship Repairs Duties

UNDERWRITERS are somewhat anxious and considerably at sea over the problems involved in the insurance liability for the 50 percent ad valorem duty provided for in the new tariff act on repairs made abroad to American ships. Evidently the same question has perplexed London, for the Institute of London Underwriters has written to the Board of Underwriters of New York asking for the comments of American underwriters on the subject, and particularly as to whether the 50 percent duty would be claimable under hull policies. A committee of the New York Board is co-operating with Manager L. J. Brengle, representing the American Marine Insurance Syndicates, in securing legal advice on this question. The lawyers are now engaged in the preparation of their opinion.

There are two sections of the new tariff which have given rise to the discussion—Section 3114 and Section 3115. Underwriters feel that the language is ambiguous, and that there will have to be definite Treasury rulings before insurers or ship owners can determine to what extent duty is payable. They want to know just what is intended by the term "stress of weather or other casualty." Again, the act appears to limit refund of duty to cases where the vessel has *put into* a foreign port, but does not make mention of accidents *while at* a foreign port. Further, the act provides that duty is refunded on such repairs as are necessary to secure the *safety of the vessel to enable her to reach her port of destination*. Hence the query, what of the case where a vessel is able to reach her port of destination abroad, but must make repairs to enable her to complete her return passage? In such instances will our Government refund on all repairs made necessary to complete a return passage with cargo? Again, what is the proper meaning of the term "destination"?

In early December certain amendments were promulgated by an Assistant Secretary of the Treasury, but these were merely to elucidate customs procedure and in the nature of instructions as to methods to follow; underwriters dismiss them as throwing no light upon the problems above outlined, and await the advice of their counsel and pertinent Treasury rulings.

Negligence Voids General Average

THERE is no application of the doctrine of general average when the necessity for the sacrifice was caused by the negligence of the master or the crew. Such is the decision made in the *Mary F. Barrett* case, 270 Fed. Rep. 618. Before the Harter Act was passed ship owners were unable by contract to relieve themselves of liability for such negligence. That act exempts vessels from liability for losses due to errors of navigation, but does not entitle them to general average contributions for losses resultant therefrom.

If there is no stipulation in the charter-party entitling the ship to general average contributions on this account, a stipulation authorized under the Harter Act, the vessel cannot, on a libel for part of the cargo jettisoned because of the stranding of the ship resultant from errors of navigation, interpose the right to general average as a defense *pro tanto*.

Buffalo Lay-ups

BECAUSE of the serious losses sustained by the breaking of the Buffalo breakwater last winter, underwriters have disapproved of that port for the laying up of vessels and have imposed an added three-quarters of one percent for coverage there. The Great Lakes Protective Association has taken this very much to heart and has pronounced it unjustifiable. They object to the dictum of the insurers that the berths be limited to fifty-five, and urge a further extension of the mooring space. They also ask that if this additional premium must be paid it should be on a pro rata basis with a minimum lay-up of fifteen days. Otherwise, they insist, no differential exists as between a season lay-up and one for a week.

The Maritime Association of the Port of New York to Celebrate Fiftieth Anniversary On February 5

THE Maritime Association of the Port of New York will celebrate its fiftieth anniversary with a banquet at the Hotel Astor on February 5. This body today is one of the most powerful organizations in the shipping industry in the Western Hemisphere.

For some years prior to 1872, a number of merchants interested in shipping congregated at the corner of William,

The rooms of the new organization, owing to its increased membership, soon became inadequate and an agreement was made with the Merchants' Exchange and News Association to rent for three years, from May 1, 1874, to May 1, 1877, the ground floor of 66 Beaver street, running through the

C. H. Potter, President

Produce Exchange. On May 1, 1875, the Maritime Association purchased the stock of the Merchants' Exchange and News Association and the membership was increased to 1,000.

John Dowd, Vice-President

W. F. Firth, Secretary

A. M. Campbell, Treasurer

South William and Beaver streets (sometimes called the downtown "Five Points"). In the latter part of 1872 it was suggested that a room be engaged in that vicinity. The idea met with very favorable response, and within two weeks, ending January 16, 1873, 140 firms had signed their names to the subscription list to defray the expenses of the new enterprise. The Maritime Association of the Port of New York was then formally organized and rooms engaged at 61 Beaver street, the formal opening being held on February 5, 1873, at 3 p. m.

In 1903 negotiations were made to purchase the property at 78-80 Broad street which proved successful and on January 5, 1904, the formal opening of the new quarters was celebrated by the first banquet of the association, which was held on the floor of the exchange.

On April 25 of this year the list of membership was raised from 1,200 to 1,500 to further increase the scope of the organization by additional members in the fast growing field of shipping. There are at the present time 127 shipping and allied trades represented in its membership.

Shipbuilding in the United States in 1922

Private American Shipyards Delivered 303,433 Tons of Shipping Last Year—503,238 Tons Now Under Construction

ADVERSE financial and business conditions abroad, coupled with the Naval Disarmament program entered upon in 1922, have wrought havoc in the activities of American shipyards during the last year and their output of vessel tonnage has dropped to the average of pre-war years when their facilities for building ships were far less extensive than they are now.

During the year just ended, private American shipyards turned out a total of 256 vessels of over 100 gross tons each, aggregating 303,433 tons. Of this output, 230 were merchant vessels of 282,938 gross tons and 26 were naval vessels of 20,495 tons. The output of the individual yards is shown in the table on the opposite page.

Of the tonnage built, approximately 67 percent was turned out on the Atlantic and Gulf coasts, 11 percent on the Pacific coast, 8 percent on the Great Lakes and 14 percent in the Mississippi Valley, as follows:

Distribution of Shipbuilding in 1922

District	Tonnage	Percent
Atlantic and Gulf Coasts.....	204,257	67.3
Pacific Coast	33,143	11.0
Great Lakes	23,223	7.7
Mississippi Valley	42,810	14.0
Total	303,433	100.0

TONNAGE NOW UNDER CONSTRUCTION

The volume of tonnage now under construction in private American shipyards aggregates 503,238 tons, of which 233,096 tons are merchant vessels of over 100 gross tons each and 270,792 tons are naval vessels. Approximately 65 percent of the work now in hand is being built on the Atlantic and Gulf coasts, 11 percent on the Pacific coast, 14 percent on the Great Lakes and 10 percent in the Mississippi Valley, the tonnage being distributed as follows:

Distribution of Shipbuilding on January 1, 1923

District	Tonnage	Percent
Atlantic and Gulf Coasts	328,315	65.0
Pacific Coast	56,224	11.2
Great Lakes	69,250	13.8
Mississippi Valley	49,449	10.0
Total	503,238	100.0

As compared with the present volume of tonnage under construction, there were building in private American shipyards a year ago 792,976 tons of shipping, comprising 322,680 tons of merchant vessels and 460,296 tons of naval vessels.

LEADING SHIPYARDS

Considering the volume of output of the individual shipbuilding companies, the leading position last year was held by the Bethlehem Shipbuilding Corporation, Ltd., with a total output of 126,242 tons of both merchant and naval vessels. The New York Shipbuilding Corporation was second with an output of 32,622 tons comprised wholly of merchant vessels.

This year the Bethlehem yards again lead with a total of 155,092 tons of vessels under construction and the New York Shipbuilding Corporation is second with a total of 80,132 tons. In both cases the work includes both merchant and naval construction, the various yards of the Bethlehem Shipbuilding Corporation, Ltd., having 41,700 gross tons

of merchant vessels under way and 113,392 tons of naval vessels while the New York Shipbuilding Corporation has 12,132 tons of merchant vessels under construction and 68,000 tons of naval vessels.

Considering merchant vessels only, the American Shipbuilding Company on the Great Lakes is in the lead with a total of 46,200 gross tons under construction as against the Bethlehem yards with 41,700 tons of merchant work. The company with the third largest volume of vessel tonnage under construction is the American Bridge Company, which is building 34,180 gross tons of barges.

CONTRACTS PLACED IN 1922

Over \$32,500,000 worth of new vessel construction was placed in American shipyards during 1922, according to data compiled from the records published in our columns from month to month. In the list of new steamship contracts, the most important placed during the year included two passenger steamers for the Cleveland and Buffalo Transit Company to cost approximately \$6,000,000; three freight ships for Great Lakes service, \$2,400,000; four Diesel electric dredges for the United States Government, \$2,528,240; two passenger ships for the Seaboard-Day Line, \$2,000,000; two passenger ships for the Savannah Line, \$1,840,000; two passenger ships for the Merchants and Miners Line, \$1,700,000; three ferries for the city of New York, \$1,589,900; a new steamship for the Inter-Island Steam Navigation Company, \$1,027,000; two ships for the United States Steel Products Company, \$1,000,000 and a new steamer for the Pacific Cable Company, \$1,000,000.

In addition to new vessel construction, American shipyards received contracts during 1922 for nearly as much vessel reconditioning work. A total of more than \$84,981,517 worth of vessel construction and reconditioning work in contemplation was reported in our columns during the year and over \$50,242,824 in contracts placed for similar work.

PROSPECTS FOR 1923

Unmistakable signs indicate that the year 1922 marks the low point in shipbuilding in the United States and that 1923 will produce a considerably larger amount of construction. Among the first contracts to be placed with American shipbuilders in 1923 are those for two passenger ships for the Eastern Steamship Company at a cost estimated at \$4,000,000; a new passenger and freight ship for the New York and Porto Rico Line, \$1,500,000; and a new passenger and freight ship for the Clyde Line which is expected to cost in excess of \$1,000,000. From present indications the contracts for these vessels will be placed during the first half of the new year.

In addition to this new construction work, which at the present time seems practically assured if present plans are carried out, \$6,500,000 worth of ship reconditioning work, involving the steamships *Agamemnon*, *Mount Vernon*, *President Grant* and *America*, will also be in the hands of American shipbuilders during the early part of 1923. It is also evident that 1923 will bring forth not only additional sea-going vessels but river and harbor craft as well, there being a strong tendency in those localities requiring shallow draft steamers to dispense with wooden vessels in favor of steel.

engines and equipped throughout with electrically-driven auxiliaries is contemplated by the Bureau of Lighthouses of the Department of Commerce, Washington, D. C.

According to the annual report of the Commissioner of Lighthouses to the Secretary of Commerce the increasing need of additions to the vessels of the Lighthouse Service will involve an expenditure of approximately \$3,260,000 during the next three years for new vessel construction and appropriations for a part of this program will be requested at once.

VESSELS FOR WESTERN RIVERS

Appropriations, totaling approximately \$1,000,000, are expected to be available for work in the Mobile district of the War Department during 1923. The Engineer Office in that district has under construction at the present time a 100-foot Diesel electric stern wheel tug with steel hull having a length overall of 119 feet, beam, molded, 23 feet and depth, 5 feet. The contract for the construction of this vessel was recently awarded to the Charles Ward Engineering Works, Charleston, W. Va., for a total of \$89,000. The same office has also recently placed contracts for the construction of 62 hydraulic pontoons at a total cost of \$22,568 and expects to advertise for bids during the early part of 1923 for the construction of 7 steel barges, 100 feet by 25 feet by 5 feet and has plans under course of preparation for a steel derrick boat.

MOTORSHIPS CONTEMPLATED

The Atlantic and Western Steamship Company, commonly known as the Nawsco Line, which is engaged in coastwise service between the Atlantic and Pacific coast ports of the United States, contemplates the purchase of vessels from the Shipping Board for conversion to Diesel propulsion.

The Rochester Terminal and Canal Corporation, Rochester, N. Y., it is understood, is planning the construction of new barges and the conversion of coal burning tugs to either oil burning or Diesel equipment.

The United States Engineer Office, Portland, Ore., contemplates the construction of two steel dump scows, each 70 feet long, 22 feet wide and 6 feet deep, and the Engineer Office, Jacksonville, Fla., is planning to construct three steel barges, each 80 feet by 26 feet by 5 feet, and a motor dredge tender.

It is learned that the Port Huron and Sarnia Ferry Company, Port Huron, Mich., contemplates the purchase of a boat with a capacity of from 750 to 1,000 passengers for ferry service, to be ready for operation in the spring.

While there is a possibility that S. Sgitovich & Company, steamship agents and operators, at Galveston, Tex., may acquire ocean tonnage in the near future, definite action has not yet been decided upon.

The Goodrich Transit Company, Chicago, Ill., while having no definite building program in view for new vessels, is considerably interested in fuel oil burning. Several passenger vessels on the Great Lakes are being converted from coal to oil this winter and the Goodrich Company will probably watch with interest the results of these conversions.

British Shipping and Shipbuilding in 1922

**Obsolete Tonnage Greater Than Most People Believe
—Rush of New Contracts in Final Quarter Significant
That Trade Improvement Will Increase Building Costs**

By W. H. Wendon

SHIPOWNERS and shipbuilders of the United Kingdom enter 1923 with measurably more hope in their minds than when they embarked on the year through which we have just passed. 1922 started badly, and retained a deplorable slumpiness for the greater part of its natural course, but fortunately towards the close of the year a brighter aspect ruled—hence the feeling of better times in store in the not too distant future. Not that *all* owners and builders hold this view; on the contrary, there are some who see nothing but gloom in the year which lies before us. What has given rise, more than anything else, to the conflicting opinions which now obtain in shipping circles is the advisability or otherwise of certain owners who have deemed it expedient to contract for new vessels.

These new contracts—so conspicuously few in the earlier months—came with somewhat of a rush in the final quarter. The owners were apparently uninfluenced by the still enormous quantity of steamship tonnage laid up in various parts of the world (the amount of merchant shipping laid up all over the world is estimated at round about ten million tons gross) and the fact that rates of freight remain on an unremunerative level.

Some shipbuilders are willing to accept as low as £8 10s. per ton deadweight for a steamer to carry 8,000 tons, and with delivery about June, 1923. Several contracts have, in fact, been placed at between £8 10s. and £8 15s. per ton—prices which will mean a substantial loss to the shipbuilders. The view of shipowners who are thus contracting would seem to be that as, apparently, prices have reached bottom—at all events for the time being—it is advisable to order vessels in the hope that by the time the boats are constructed the general position will have improved.

BUILDING COSTS WILL NOT GO LOWER

The views of one shipowner of many years' experience in the placing of contracts are not devoid of interest. He states that, while, compared with pre-war prices, the present cost of building seems very large, being about thirty percent above pre-war, he does not see how values can fall to anything like those existing in 1914, owing to the cost of coal, increased railway rates, extra wages, etc. This shipowner describes the position of the Continent as "about as bad as it can be," and that any change must be for the better. Europe, he points out, still wants a mass of material of one description or another, and, once its inhabitants are in the position of getting to work on pre-war lines, trade will improve. He places against the amount of the laid-up tonnage in the world the obsolete tonnage, which, he considers, is greater than most people realize.

Then there enters into the question the highly important matter of the future of the Diesel-engined vessel. Shipowners as a body are now convinced that the ship of the future is the motorship. Probably it only requires one or two owners to be successful with the operation of internal combustion engined vessels for the rest of shipowners to lay down similar boats, but in the meantime there is—perhaps not unnaturally—a marked reluctance on the part of shipowners to act as "pioneers" in this matter. They *feel*, as I have indicated, that the future of the motorship is assured, but beyond that they are not prepared to go. It is considered that developments in Diesel ships will enable owners to

earn dividends even at current freight rates, which show a loss when accepted by the older boats, but shipowners as a body have reached the decision that before contracting, it is their duty to themselves and their shareholders to inquire closely into the working costs of such boats as compared with vessels already in their lines. Several of the leading owners, however, have given it as their intention, if the figures are satisfactory, to build one Diesel boat to test its efficiency, notwithstanding that the cost of the job may be as much as forty percent above that of a boat fitted with triple expansion engines.

RAPID GROWTH OF OIL BURNERS

The annual report of Lloyds' Register of Shipping, issued towards the close of 1922, gave striking confirmation of the revolutionary change which took place in marine bunkering methods during the year and its immediate predecessors, more than half—55 percent, to be exact—of the total tonnage of new vessels classed during the year ending June 30 being fitted for burning oil fuel. The rapidity with which the change has come about may be judged from statistics of tonnage equipped for oil burning on July 1, 1914, and last July respectively, the pre-war total being only 1,310,209 tons gross, whereas by July, 1922, this had grown to the enormous figure of 14,464,162 tons—or more than ten times the figure of eight years ago.

In closing my remarks on this particular phase of shipping and shipbuilding activity during the past year, I may, perhaps, be pardoned for placing on record the views on this subject of no less an expert than Sir Charles Greenway, Bart., the chairman of the Anglo-Persian Oil Company, Limited, who is of opinion that "the substitution of oil for coal is an important step towards the conservation of the world's supplies of the latter product, and, though burning oil beneath boilers is not the most economic, nor, therefore, the most desirable method of utilizing the energy contained in the fuel, this method has at least the argument in its favor that the fuel oil is a residual product left after the more valuable fractions have been extracted, whereas with coal a whole series of by-products as well as a considerable portion of its thermal efficiency are being wasted when used in its present state. It is gratifying, however, to see the strides that have been made within recent years towards the economic utilization of oil as a fuel by means of the introduction of the internal combustion engine, the increased adoption of which is shown by the fact that there were 1,620 motor vessels of an aggregate tonnage of 1,542,160 at July last, as against 297 vessels aggregating 234,287 tons in July, 1914."

BUILDING VESSELS ON SPECULATION

Another outstanding feature of the past year has been the attempt which has been made at various times to induce shipbuilders to construct steamers on "spec.," that is to say, the builders were to lay down the vessels on the off-chance that, when the boats were ready for delivery, the general position would have improved, thus enabling the builders, by persuading shipowners to acquire the boats, to realize for themselves a profit, however small, as a reward for their enterprise. Contrary to pre-war experience, when this method of transacting business was considered, more or less, to be

the proper one, shipbuilders nowadays show something amounting to keen disinclination to enter into such commitments. Not in every instance, it is true, for Messrs. Swan, Hunter and Wigham Richardson, whose magnitude as ship constructors may be gaged from the fact that during 1921 they launched no fewer than fourteen vessels aggregating 92,315 tons gross, and the even more imposing figure of 109,932 tons in the preceding year, have decided to take the risk of building, at their Wallsend yard, two vessels for their own account. They hope for such co-operation of the employees, by putting in good and energetic work, as will reduce the risk of loss, and encourage further similar experiments.

PRE-WAR WAGE SCHEME FAILS

Most important of all in the matter of projected "spec." contracts, however, was in the case of Messrs. Lithgows, of Port Glasgow, who, in the late summer, offered to lay down four cargo steamers on "spec.," provided the workers agreed to accept pre-war wages, plus any bonuses to which they were entitled. Messrs. Lithgows were obviously taking a considerable risk, for, even with steel down to a new level, and wages at pre-war rates, the boats would cost more to construct than shipowners might be disposed to pay for them in the open market. The matter did not proceed very far, however, for the employees, acting, apparently, under the fear that, if the offer were accepted, the position of their fellows elsewhere might be prejudiced, declined to fall in with the shipbuilders' scheme. The large financial risk which the employers were prepared to face carried no weight with the workmen or their trade unions, and the motion was lost to the hair-splitters.

Later in the year the suggestion came up again, when a Greenock municipal official suggested that, in order to relieve unemployment in the Scottish port, the local municipal corporation should accept responsibility for laying down three cargo steamers, of about 10,000 tons deadweight each, on the chance of somebody purchasing them either during construction or when completed. It was estimated that the adoption of the scheme would give employment to 1,800 men for at least six months, and would save the community about £34,000 in unemployment compensation. The suggestion fell on deaf ears until a Glasgow shipowning firm, stating that they contemplated the construction of three fruit-carrying steamers, expressed the desire to have the vessels built under the Corporation's scheme. Inasmuch as the plan failed to elicit marked approval on the part of the shipbuilders, it is felt that little or nothing will come of the project.

IDLE TONNAGE

There have been singular ups and downs in the figures of idle tonnage during the past year, but it may, perhaps with some justification, be taken as a good omen that, at the date of the last count, namely, October 1, there was an appreciable decline as compared with three months previously. The subjoined analysis of the tonnage laid up in the principal ports of the United Kingdom gives the position in a nutshell:

1921	No.	British Tons net.	No.	Foreign Tons net.	No.	Total Tons net.
July 25	883	1,650,788	140	201,624	1,023	1,852,412
October 25 ..	654	1,158,425	88	137,811	742	1,296,236
1922						
January 1 ...	621	1,179,548	91	128,045	712	1,307,593
April 1	422	734,240	62	102,379	484	836,619
July 1	533	1,025,662	50	86,670	583	1,112,332
October 1 ...	419	752,469	37	72,155	456	824,624

These figures, it will be noted, are all in *net* tonnage, so that about 60 percent should be added to arrive at the gross register tonnage. The table shows that on October 1 the amount of tonnage lying idle in the principal United King-

dom ports was 287,710 tons net (representing 127 vessels) lower than at July 1.

FREIGHT RATES

Closely allied to laid-up tonnage statistics are those concerning freight rates, and the fluctuations which have taken place in voyage freights and time charter freights in the last two years are interesting, 100 being taken as representing the rate in 1920. In this connection the following are vouched for by the Chamber of Shipping of the United Kingdom:

1921	Freights	Time charter
January	46.3	59.8
February	38.0	41.8
March	37.5	39.8
April	39.5	39.5
May	39.4	37.4
June	42.7	36.6
July	43.0	34.7
August	40.2	34.7
September	34.4	33.9
October	30.8	29.9
November	29.8	29.9
December	33.3	29.9
1922		
January	33.0	29.9
February	33.6	29.9
March	33.3	29.9
April	31.0	28.4
May	32.5	26.9
June	29.8	26.1
July	27.8	35.4
August	27.6	25.4
September	26.7	25.4
October	28.1	23.9

It will be observed that in October, the latest month for which complete data are available, freights moved up nearly two points as compared with the preceding month, but that the time charter rate had a disastrous setback at 23.9, as against 25.4 in each of the two preceding months. It would, indeed, be necessary to go back practically to pre-war days to run across a time charter as low as that current last October. Comparison of the 23.9 of October with the 59.8 of January, 1921, indicates very clearly the fall which has taken place.

REGULATIONS FOR DISCHARGING OIL

1922 saw a great step in the right direction *apropos* the discharging of oil and oily waste in docks and harbors. After a prolonged period of negotiation a scheme was at last put on foot, with the result that, as from January 1, 1923, it is unlawful under the "Oil in Navigable Waters Act" to discharge oil and oily waste from vessels in territorial waters, the aim of the measure, of course, being to put a stop to the danger to dock and shipping property arising from such discharge. These regulations were published in full in the November, 1922, issue of MARINE ENGINEERING AND SHIPPING AGE.

PORT CHARGES

While shipowners and port authorities have had a measure of unanimity on one matter, it cannot be said that their views coincide in relation to another. They are, in fact, a long way from seeing eye to eye on the question of port charges, and during the year through which we have just passed the arguments at times have been, perhaps, more pointed than polite. The various port authorities have made substantial reductions in their charges, but still not to the requirements of the shipping community, who see in port costs the biggest bill in which a cut should be made. There is certainly some justification for their contention that, while freight rates have slumped enormously, port rates in many instances remain at least double the pre-war figure.

Port authorities, however, are determined, if at all possible, to adhere to their present charges, and have applied

to the Ministry of Transport for permission to continue the existing increased charging powers. The history of these powers is of more than usual interest, in that it shows what may result from the institution of so-called "temporary" measures. Briefly, then, the powers were conferred by the Harbors, Docks and Piers (Temporary Increase of Charges) Acts, 1920-22. Shipowners and traders generally have now the right to object to the continuance of these higher charges, and, where such objections are made, the Minister of Transport must refer them to the Rates Advisory Committee, before which the objectors have a right to be heard. Thus it rests with those engaged in the shipping industry to take action, as otherwise it might be assumed that the application of the dock and harbor authorities would meet with the sanction of the Ministry of Transport.

In September, 1920, the Minister of Transport directed railway companies to increase the charges at their docks by 150 percent above the pre-war rate, the object being to prevent any further losses to the taxpayer during the period of Government control. On the de-control of the railways in August, 1921, the companies were permitted to continue the increased charges until February, 1923. In the case of the non-railway-owned docks, orders were made at various dates by the Ministry of Transport under the Act permitting them to make increased charges. These orders also were terminable in February, 1923.

In the last session of Parliament the Minister of Transport introduced a bill to continue the Harbors, Docks and Piers (Temporary Increases of Charges) Acts until February, 1925, but this Bill was amended, with the result that the Act of 1922 empowered the Ministry of Transport to continue the increased charging powers for both classes of docks only until February, 1924, with the proviso that shipowners and other parties interested should, as I have pointed out, have the right to object to such orders being made. There is ample evidence, therefore, that, unless the port authorities are induced to change their minds in the matter of charges, there will be some lively exchanges of opinion between the authorities and their shipping clients.

The battle for the title of "Premier Port of the United

Kingdom"—if not of the world—has been carried a stage further than could be recorded this time last year, for in the intervening period London, Liverpool and Southampton have wrestled with each other in an endeavor to secure pride of place. But the main issue, so far as mammoth dock construction is concerned, would seem to lie between Liverpool and Southampton—the former in respect of its Gladstone Dock, which is undergoing extension and improvement to enable the largest vessels in the world to find accommodation, and Southampton in regard to the huge floating dry dock, the contract for which was placed with Sir W. G. Armstrong, Whitworth and Company, Ltd., Newcastle, late in the past year.

The London and South Western Railway Company, who handle the shipping traffic at Southampton, reached their decision to build the dock in June last, and the dock is intended to accommodate the largest Transatlantic liners, including the *Majestic*, *Berengaria*, *Aquitania* and *Mauretania*. Every effort will be made to put the dock in commission before the close of 1923.

Increased capitals and reduced dividends have been the outstanding features of shipping companies' balance-sheets. Many millions sterling have been subscribed by all and sundry at the invitation of shipping companies—principally the larger liner concerns—the sums being needed, in the majority of instances, to enable the companies to pay for boats contracted for when prices were high.

In conclusion, while the shipping and shipbuilding companies of the United Kingdom experienced in 1922 a lean time, they are certainly not worse off than some of their Continental competitors, whose troubles have also been great. Exception may, perhaps, be made in the case of Germany, but so far as that country is concerned, everything in a business way is purely artificial. The "value" (save the mark) of the mark has placed German builders, owners, repairers and breakers in an advantageous position as compared with those in other countries, but, on the other hand, the domestic calls have been heavy, and it must be solely a matter for conjecture as to the *real* benefit, if any, which has accrued to German business men.

First Landing of Land Plane on Deck of United States Warship

In successful naval maneuvers held recently aboard the U. S. S. *Langley* in the York River, Virginia, a land-type plane for the first time landed successfully on the deck of a United States warship. Lieutenant Commander Godfrey DeC. Chevalier, flying the two-seater A-606, landed on the flight deck of the U. S. S. *Langley* while the vessel was proceeding at a speed of about six knots.

The Situation in German Shipyards

**Shipowners Prevented from Placing Contracts
by Depreciation of Currency Which Makes It
Impossible to Estimate Cost of New Vessels**

By K. Trautner

THE general slump in shipbuilding throughout the world has begun to make itself felt in German shipyards which until a few months ago were still sufficiently busy. The reason for this situation is to be found in the fact that the indemnities that the Federal Government had to pay to shipowners by way of compensation for merchant ships seized and delivered to the Entente have been for the most part used up and so far no further grants have been allowed due to the government being overburdened with reparation payments.

In foreign papers the opinion has been expressed of late that the Federal Government is supporting shipowners by means of high subsidies, thereby enabling them to rebuild a large merchant fleet in a comparatively short time. This, however, is not the case; it was merely a matter of indemnities, to which shipowners had an equitable right for the ships that had been taken from them. Furthermore, the sums paid were so extremely small that only a very small fraction of the 1914 tonnage could be rebuilt. Most of these replacement ships are already in operation and the balance is going to be ready within a comparatively short time.

POSSIBILITIES FOR NEW CONTRACTS

As to the securing of further shipbuilding contracts, great difficulties lie in the way of the shipyards. In particular it is thoroughly impossible in view of the daily repetition of further slumps in the value of German currency to make any safe reckoning and to submit firm offers for the building of new ships. The shipyard is therefore unable to give to the shipowner the slightest information as to the final cost of his new ship and this insecurity makes it impossible for most shipowners to place shipbuilding contracts unless they are to be paid for out of indemnities paid by the Federal Government.

Furthermore, the financial situation of practically all German shipowners has been so seriously impaired by the war that many of them were compelled to meet their most urgent requirements by refitting old ships or by making purchases abroad. It is therefore seen that the future prospects of the German shipbuilding industry are not particularly promising.

The river shipbuilding yards are still partly busy on reparation building for the Entente. This building consists mainly in river tugs and freight barges for the Rhine and the Elbe and also for the Danube.

A special type of river tow barges, many hundreds of which are to be delivered to France and to Belgium by way of reparation, consists in a type of barge having the following measurements:

Length between perpendiculars	About 124 feet 8 inches
Molded depth	About 16 feet 5 inches
Beam	About 7 feet 6 inches
Displacement	450 tons
Draft	About 7 feet 3 inches

These vessels are provided with living quarters astern and with cargo space forward. At the bow there is fitted up a small iron warping winch with 4 warping ends and amidships there is a portable mast.

FOREIGN CONTRACTS AT HAMBURG

Among German shipyards the Deutsche Werft of Hamburg alone can boast at the present time of having succeeded in

securing some large contracts from abroad. These contracts are the following: 2 Diesel motorships of 21,000 tons dead-weight each, ordered by the Swedish shipping firm of Broe-stroom of Gothenburg, and, furthermore, 2 Diesel motorships of 6,000 tons each for another Swedish company. Another Hamburg shipyard is negotiating for the building of a large freight and passenger ship which is to be built for Italy on reparation account.

SHIPBREAKING

Several other shipyards have taken up as a side line to procure work, the demolition of old or uncompleted war vessels, both domestic and foreign. Among these old war vessels particular mention should be made of the Russian armored cruiser *Askold*, of 24 knots speed and 6,100 tons displacement. This ship, distinguished by its five funnels, was one of the few vessels that was able to reach a neutral port after the battle before Port Arthur had been lost in the Russo-Japanese war.

(Photograph by Kadel & Herbert, N. Y.)

Germans Salvaging Ships Sunk Ten Years Ago for Their Iron and Metal

Due to the scarcity of iron and metal in Germany, concerns are now raising old ships that were sunk years ago to get the iron and metals. The above photograph shows the huge derrick pulling up the hull of a ship sunk ten years ago in the Kiel Canal.

FORMER NAVY YARDS CONSTRUCTING AUXILIARIES

The former Imperial shipyards of Kiel and Wilhelmshaven are engaged, aside from shipbuilding, in the construction of auxiliary engines, motors, stationary engines, etc.

While until a few months ago many foreign shipowners had their ships dry-docked in German ports, this work has likewise experienced a heavy decline, due to prices in Germany having risen so high of late that many foreign ships find it cheaper to use their domestic rather than German dry docks. Many docks, therefore, remain empty.

Considering all circumstances, German shipyards are looking forward to a dark winter. On the one hand wholesale dismissals of workmen and employees are threatened and on the other hand exorbitant increases in the prices of food, fuel and all the necessities of life, which have taken an enormous lead over salaries and wages.

New Cable Ship Marie Louise Mackay

THE *Marie Louise Mackay*, a twin screw telegraph cable repairing steamer which has been built and engined by Swan, Hunter & Wigham Richardson, Limited, at the Neptune Works, Newcastle-on-Tyne, for the Commercial Cable Company, Limited, of New York, has recently left the Tyne.

The steamer is built of steel, being about 245 feet in length by 34 feet in breadth by 24 feet 6 inches in depth.

the vessel. A large glazed shelter on the navigating bridge may be specially mentioned, where all on duty there are well protected from bad weather. The captain's accommodation is on the navigating bridge, while the rooms for the navigating and cable officers are on the awning and main decks amidships, including a very comfortable dining saloon amidships. The petty officers, cablemen and seamen are on the main deck aft.

The steamer is also fitted with an installation of wireless telegraphy, ample ventilation, steam heating, electric light and bells, telephones, etc. There is a refrigerated room aft for the ship's use, as well as ample storeroom accommodation.

The auxiliary machinery for navigating and working the vessel is of the most improved pattern, including a specially designed steam windlass forward and steam capstan aft, steam winch, steamboat hoist, steam steering gear, motorboat, etc.

PROPELLING MACHINERY

The propelling machinery, which has been constructed by Swan, Hunter & Wigham Richardson, Limited, at the Neptune Engine Works, Newcastle-on-Tyne, consists of twin screw triple expansion engines, supplied with steam from two boilers, working under Howden's system of forced draft, and fitted to burn oil fuel on the Wallsend-Howden system.

When the vessel was at sea for her trial trip, everything worked without the slightest hitch, giving entire satisfaction to all concerned, attaining a speed of 12 knots.

Cable Ship Marie Louise Mackay

She has three cable tanks for the carriage of the submarine cable, all placed forward of the propelling machinery and having a total coiling capacity of about 18,000 cubic feet and a hold forward arranged for the stowage of cable stores, etc. The machinery for working the cables has been supplied by the Telegraph Construction and Maintenance Company, Limited, and is of their latest design; it includes picking up and paying out gears, Lucas dynamometers and a Lucas patent sounding machine. Three large cable sheaves are fitted to the overhanging bow.

Arrangements have been made for the carriage of water ballast in both the fore and after peaks and in the double bottom, while the oil fuel is carried in a cross bunker and is of sufficient capacity for a cruise of 6,000 miles.

CREW ACCOMMODATIONS

The comfort of the staff on board has been the object of special consideration in designing the accommodations of

The vessel, which has been built under the supervision of Capt. F. H. Larnder, O.B.E., is the second cable steamer recently built at the Neptune Works for the Commercial Cable Company. The other, a much larger steamer, called the *John W. Mackay*, has made a very successful beginning to her career since her delivery to her owners early in June last year.

New Port Association Proposed

Frank S. Davis, manager of the Maritime Association, Boston Chamber of Commerce, has invited port organizations at the several North Atlantic ports to convene for the purpose of organizing a North Atlantic Ports Association. The meeting will probably be held in New York City in the near future, when the aims of the association will be disclosed and officers elected.

Efficiency in the Operation of Steamships

Analysis of Operating Costs Shows Where Economies Can Be Effected—Why American Ships Need A Subsidy

By Captain Daniel A. J. Sullivan†

SINCE the inception of transporting freight by means of water routes until the present time, there has been one important question which has caused more worry and deep study than any other, and that is the cost of operation. In the study of this subject one is impressed with the importance of every detail which added together makes the whole, so that in delving into the records of the past, those of us who are now striving to produce efficiency realize the necessity that each and every member of the profession should understand that his efforts and his labor are a part of the whole, and if the results of his labor are not up to the mark, then the whole will be handicapped by just that amount. So in the efficient operation of any ship, every person who has had a part in designing, in building and then in operating that ship is responsible for his part, and if each and every one has produced perfect results then the result as a whole should be perfect.

In theory this is true, but in practice we find too many "exceptional conditions," which expression has been used to cover a multitude of blunders in the past as well as in the present. So in the study of this subject we must admit to ourselves that each of us is responsible for the results attained, and that on the blunders of the past we can erect a perfect organization for successful operation.

The history of shipping reveals many interesting events, and without spending too much time on the past, it is well to recall that supremacy of the seas has gradually changed from nation to nation since the beginning of water transportation until the present, and will continue to be fought out on economic lines until the end of time. In studying the cause of the gain or loss of the supremacy of the seas, it appears to be true that the nation which can build ships for less than others, and whose vessels can transport cargoes faster and cheaper than others, will rule the sea. Here again enters the "exceptional condition" in the form of Government ownership and of Government subsidy.

At the time of writing this article, an effort is being made to place the merchant marine of the United States on an equal competitive basis with the merchant marine of other nations by the adoption of a ship subsidy. Those interested in the success of vessels under the American flag realize the necessity of this measure.

WHY A SHIP SUBSIDY IS NECESSARY

First, on account of the higher first cost of the vessels built in the United States.

Second, the American merchant marine is the only important American industry not protected by tariff.

Third, to equalize the present unfair competition on account of the subsidy paid to the merchant marine by other nations in competition with the merchant marine of the United States.

Fourth, on account of protection to other industries the standard of living of its employees is raised to a much higher level than the standard of living in any other country, and it is unfair to the seafaring profession to force them to a standard of living which would not be tolerated ashore.

Many critics of American shipping insist that Americans cannot operate ships. These gentlemen forget the records of the past, the most interesting of which is the era of the clipper ship, which commenced prior to the War of the Revolution and continued until just after the Civil War, when the era of steam vessels began. The years between 1843 to 1869 are to all Americans who love the sea the most interesting, as during this time American shipbuilders constructed the finest models of sailing ships ever launched. With these ships the American shipmaster proved himself superior to any shipmaster in the world, and it is a matter of record how American clippers were loading in China ports at higher freight rates while vessels of other nations could not get cargoes in the same port at lower freight rates, owing to the difference of speed, and here it may be well to quote from "The Clipper Ship Era," by Captain Arthur H. Clark, published in 1910.

"Of the men who commanded the American clipper ships, it may be said that they carried the ensign of the United States to every quarter of the globe, with honor to their country and themselves. Each had his strongly marked individual traits of character and his human weaknesses. Nothing could be more remote from the truth than to imagine these men as blustering bullies at sea or rollicking shellbacks on shore; neither were they Chesterfields or Carpet Knights, afloat or ashore, nor at all the type of skipper that one is apt to meet in works of fiction. Many of them might easily have been mistaken for prosperous merchants or professional men, until a more intimate acquaintance disclosed the aura of salted winds and surging seas, and a world-wide knowledge of men and cities. It may well be doubted whether braver, truer-hearted gentlemen or finer seamen than many of the American clipper ship captains of half a century ago have ever sailed the seas."

When these men won the supremacy of merchant shipping for American vessels it was said of them in 1860 by a critic of the merchant marine of another nation: "We have no masters who can match the masters of American vessels, and until we do, and allow them full control of our vessels, we cannot compete successfully."

Even in those early days it was thoroughly understood that the success or failure of the venture was solely in the hands of the master.

Succeeding the era of clipper ships came the era of steam, and as other nations built and operated steamships the American ensign gradually faded from the sea, and the year 1913 saw American shipping at its lowest mark.

OCEAN SHIPPING DURING AND AFTER THE WORLD WAR

The World War commenced in 1914 and naturally the demand for tonnage grew, and as the demand increased the rates soared. Since everything connected with the shipping interests follows closely the law of supply and demand, the operating cost during the war period attained such heights as to be unbelievable. During this period of inflated prices, as a defensive measure, America had constructed a large number of vessels, and when peace was declared America found herself in possession of one of the greatest merchant fleets the world had ever dreamed of. It then became a problem how to make the best use of this fleet.

It is useless to attempt to conceal the fact that at this time there existed many steamship companies, whose organizers and officials knew little about the shipping business and less

*Paper read before the Society of Naval Architects and Marine Engineers, New York, November 9, 1922.

†Commodore of the Black Diamond Steamship Corporation, New York.

about the traditions and established customs of the sea. Wages soared, conditions afloat and ashore became impossible, operating costs were excessive, claims for cargo damage and loss were unreasonably high, and with the perfection of systems of communication the status of the master and officers was reduced to practically that of a high priced office boy—obeying orders issued from ashore by those who were intoxicated by high freight rates and large profits, who thought more of the American dollar than they did of the safety of the vessel or its mark. However, as freight rates decreased, it was realized that steamship companies founded on inexperience could not endure, and it is to the credit of the profession to say that ability, experience, and efficiency are being recognized and will eventually regain control.

During the past two years, rates have fallen to the level of, and in some instances to a point lower than pre-war rates, and in the struggle of American vessels for existence in the shipping world against the bitter competition of foreign vessels which enjoy a lower operating cost, as well as a government subsidy, American shipping has reached that stage where the cost of efficient operation means success or failure to our merchant marine as a whole.

It is a fact that, among the various grades of ship officers, the American merchant marine can boast of having many who are efficient, but unfortunately many masters lack sufficient business training, due to the modern method in steamship offices where the master is not allowed to handle details with which he should be familiar, and naturally in this connection the shipowner is standing in his own light.

COMPARATIVE COSTS OF OPERATION IN THE TRANSATLANTIC TRADE

To establish a basis of comparison of the cost of operation for all classes of ships is an impossibility, and after considering the mass of data available it was decided that each vessel was an individual study.

Herewith are presented data of three vessels in transatlantic trade, reduced to an average of one voyage and all expenses are included; total cost represented as 100 percent:

	Example A Percent	Example B Percent	Example C Percent
Fuel	23.6	29.9	27.9
Stevedoring, tally, watching, clerks...	20.6	16.0	22.9
Wages on ship	11.2	14.4	13.0
Insurance	10.4	8.1	12.0
Wharfage	7.7	1.9	2.2
Agency and brokerage	4.9	3.4	2.7
Grain fittings	3.1	2.9	...
Food for crew	3.0	3.0	1.4
Stores deck department	2.0	2.9	2.9
Stores engine department	2.5	3.4	3.6
Stores steward department	0.2	0.3	0.25
Advertising	2.4	0.4	0.3
Towboats	1.8	1.5	1.4
Pilotage	1.3	1.3	1.4
Port charges	1.4	1.8	1.6
Repairs	1.6	5.1	3.6
Miscellaneous	2.1	3.5	2.6
Laundry	0.2	0.2	0.25
Total	100	100	100

From a study of the above data one readily sees that fuel, cost of handling cargo, wages and insurance are the most important items of expense.

FUEL EXPENSE

Fuel is the most important item of expense in operation and is a subject to which little intelligent study has been given, and while general results have been compared, very little satisfactory data are obtainable. The United States Shipping Board has just appointed a committee to study this

subject; this committee is afforded a great opportunity to render service to the profession.

The prevailing practice today is to buy fuel on a price basis, and no consideration is given to the heat units contained therein nor to the subsequent results obtained.

In vessels using oil fuel, where this fuel is carried in double bottoms, sufficient attention has not been given to the arrangements for heating the fuel in the tanks, with the result that in cold weather considerable loss occurs. However, many interested in efficiency feel that the Shipping Board Fuel Committee will submit data and promulgate a set of rules of procedure which, if followed, will greatly improve results.

CARGO HANDLING COSTS

Next in importance to fuel is the cost of handling cargo, which includes loading, checking, sorting, watching, and clerk hire on dock. Investigation revealed that the total actual cost per ton of general cargo handled in New York varied from \$1.15 a ton to \$1.65, and in the ports on the Atlantic coast the range in cost per ton was from \$0.92 to \$2.15. One interesting example is as follows:

Cargo handled 152.4 tons general.	
Stevedoring	\$137.00
Cooperage	75.00
Watching	70.00
Sorting and delivering	284.00
Total cost	\$566.00
Average cost, \$3.71 per ton.	

One only need check up on a ship during the loading and discharging to realize where the money goes. This item alone, on an average, is one-fifth to one-sixth of the total expense and is seldom checked as to delays, waiting, overtime, etc. With proper supervision, even with the high rates of pay, this excessive rate per ton could be greatly reduced.

WAGES

Third in importance in operating cost of a vessel are wages afloat. So very much unreliable data have been printed about this subject that great care was exercised to obtain only authentic data, and the rates of pay quoted on American vessels was taken from shipping articles which are on file in the commissioner's office. The rates of pay on foreign vessels were obtained from vessels in service and shipowners, and for the benefit of those who are interested the information is tabulated and herewith presented in the hope that it will speak for itself.

The standard of living in this country is so different from that in foreign countries that it is absolutely unfair to compare American wages with those of foreign vessels.

One of the most unfortunate lines of reasoning today is that by cutting wages one obtains efficiency. It matters not in what capacity a man is employed, if the wages for that rating are higher than the wages for the same ratings in other lines, then the most efficient man will be found for the place.

Perhaps the reader may find in the scale of wages herewith presented sufficient explanation as to why the native born American does not adopt the profession of the sea.

INSURANCE

Much could be written about the subject of insurance—all classes—but it would not influence the prevailing opinion of those who should know the subject fairly well. Any discussion on this subject can be summed up by saying that when loss and damage are high the rate is high and when loss and damage are low the rate is low. This cost could be reduced by bonus to ships' officers and self-insurance.

The remaining items which enter into the cost of operation are either unavoidable or under the supervision of the personnel afloat, and if care has been exercised to select only

WAGE SCALE EFFECTED ON JULY 1, 1922

	U.S.S.B. Scale	A.S.O.A. Scale	Private Owned American Actually Paid		British		German		Danish		Swedish

Messboy	35.00	35.00	35.00	35.00			1,525	3.81	...		..	

efficient officers, it naturally follows that they will produce efficient results.

SUBSISTENCE

The question of subsistence, while not very large in total cost, is most important in having satisfied personnel afloat, and sufficient care should be exercised to see that food is properly prepared and made appetizing instead of the all too common practice of serving improperly prepared and unpalatable food.

The Shipping Board has recently placed a limit on the cost of feeding of 65 cents per man per day. My experience is that this is a generous allowance, provided that it is judiciously expended.

DECK AND ENGINE STORES

In the matter of deck and engine stores it would be well to work out an annual schedule of allowances and requirements. In discussing this subject with one of the profession, I found that he had worked up data for a company covering its fleet of quite a number of vessels, and on an average the figures of cost allowance check very close for requirements. For example, a vessel of the 7,500 to 9,000 deadweight ton class was allowed:

Deck department	\$17.30 per day
Engine department	19.15 per day
Steward sundries	5.25 per day

In comparing these figures with those of actual operation, they were found to be rather generous, and it only confirms the opinion that in these departments, with a fixed schedule, the former excessive cost can be reduced to a minimum.

Taken as a whole, one is impressed with the manner in which shipping is handled since the days of the World War, and while in many cases there is too much misdirected energy, the members of the profession realize that the time has arrived to establish the American merchant marine on a clean, efficient business basis, and to regulate the operating cost so that it will be on a par with international competition.

PERSONNEL

From a study of the data available, the writer is of the opinion that American ships can be made efficient, and excepting the excessive first cost, depreciation and overhead

expense, can hold their own against any competition. To accomplish this result there should be closer relations between the executives of companies and the masters of their vessels. Masters should be selected for their efficiency and given absolute authority over the operation of their vessels. Chief engineers should be selected likewise and given absolute authority over their own department. The master should be furnished with complete cost data so that he can remedy high cost over which he has control and show the owner the excessive cost over which he has no control, so that this handicap may be overcome.

EXPERIENCED MEN NEEDED

Managers and marine superintendents should be men who have served as master of a vessel. Superintending engineers should be men who have served as chief engineer of a vessel. Everything concerning the handling and stowage of cargo should be subject to the approval of the master of the vessel. If the master is to be held responsible, he should be given full authority regarding all details involved in the operation of his vessel.

Store Nordiske, New Oil-Fired Cable Ship

Built by Nakskov Shipyard, Limited, Nakskov, Denmark, for the Shanghai station of the Great Northern Telegraph Company. Principal dimensions of the vessel are as follows: Length, 238 feet 6 inches; beam, 35 feet; depth, 23 feet 6 inches.

Fuel Economy in Shipping Board Vessels*

Methods Prescribed for Purchasing Fuel—Instructions Given for Taking It on Board and Standards Set for Burning It

By Commander R. D. Gatewood†

AN analysis of the total operating expenses or outgo indicates that fuel alone amounts to from 22 to 25 percent of the total cost of running a ship. It is more than the wages of the men, the food they eat, the repairs to the vessel and the consumable stores all combined!

Realizing this, Mr. Joseph Sheedy, who is the first engineer to be made a vice-president of the Emergency Fleet Corporation, appointed a committee known as the Fuel Conservation Committee, whose chairman is Captain C. A. McAllister. A better selection it would be hard to find. An American engineer of high attainments, he was for many years engineering head of one of the most efficient departments of the Government, and one in which the appropriations have always been pared to the bone—namely, the United States Coast Guard. His experience in keeping within the extremely limited appropriations and his natural tendency toward thrift and economy, that comes to him from his Scotch ancestry, fit him eminently well for the position.

The committee conceives its problem to be to get the most out of the ships as they now are, without the expenditure of any very considerable sums to rebuild them. The Government is mandated by Congress to sell them, and except for certain major defects which must be corrected in a given ship here and there, the Government will not receive any more money for the ship after the expenditure involved in changing a lot of the machinery of the vessels; and the committee feels that the principal problem is to bring the present equipment up to its maximum performance.

To this end, the operating fleet of 400 vessels was analyzed with regard to the kind of fuel burned, and this analysis showed that 90 percent of the vessels burned oil and only 10 percent burned coal; whereupon it was immediately decided to concentrate the major effort of the committee on oil-burning vessels.

RESULTS OBTAINED ON THE S. S. AMERICA

In order to show, however, just what could be done with coal-burning vessels, the largest coal-burner in the fleet, except one,—namely, the *America*,—was chosen as the vessel to be given special attention and study. A careful analysis of her boiler and engine department was made, and it was at once apparent that certain changes were absolutely necessary in her boiler furnaces and fronts, some minor changes in valve settings and a number of other minor adjustments here and there throughout the engine department before the vessel would be ready to perform in accordance with the standard set for that type of machinery. All this work was done at a cost of not over \$7,000 or \$8,000, and then several special expert observers were sent on her to Europe and return, every possible care being taken to fire the boilers in the most economical way and operate the department in accordance with the best known engineering practice, considering the age of the vessel.

The results were truly surprising to the lay mind, but were no greater than the committee anticipated. Here was a vessel that had been sailing back and forth across the ocean for many months, making her schedule but with apparently relatively little regard for the fine points of fuel

consumption. On the very first trip the vessel saved 400 tons of coal on the round trip. She has just returned from a second trip and made a similar saving, maintaining on both trips equal or slightly better speed than for the past four or five round voyages. The total saving on the two trips more than outweighs the expenditure involved in correcting the defects that the committee found, and the vessel will continue to operate back and forth across the ocean, saving about 500 tons a trip over previous voyages. This will serve to give some indication of the practical nature of the work of the committee and the benefits to be derived therefrom.

PERFORMANCE STANDARDS TO BE SET

The committee has further subdivided its problem into one of sea consumption and port consumption; these two problems involve study along quite different lines. Some steamship lines operate well at sea and poorly in port; others operate economically in port but are very expensive at sea. The committee is now engaged in setting a set of standards for each and every type of vessel now operating, showing to the operators and the chief engineers exactly what their performance ought to be in the amount of coal burned per mile. Heretofore there has been absolutely nothing for the engineers to work toward as a standard. Already these standards have been developed for several types, and in practically every case the vessels are found to fall well below the reasonable standard set by the committee, and already there has been a marked improvement in these types to bring up the performance of the vessels and meet the standard or better it.

The port consumption problem will be attacked in the same way, but necessarily owing to the great number of vessels and the difference in their motive power, any such problem becomes a very large one and cannot be proceeded with too rapidly. The saving in fuel that may be possible is, however, a great incentive to the committee, for the reason that our fuel bill for last year was between \$35,000,000 and \$40,000,000, and if, as is confidently believed, we can save 10 percent of this amount, a truly creditable piece of work will have been accomplished.

EXPERT FUEL INSPECTORS APPOINTED

The committee began its work by an analysis of the specifications for the fuel and an examination into how it was purchased and inspected, and it was at once apparent that while the specifications were apparently adequate and sound and conformed to the specifications in the general business and governmental world, there was not an adequate staff to insure that the material actually purchased was in every case in accordance with the specifications. As a result of the work of the committee, expert fuel inspectors have been appointed at several of our principal ports to insure the best quality of fuel being obtained and placed on our vessels.

The next step of the committee was to standardize instructions for engineers for taking the fuel on board. Many lines had no specific instructions at all, and in no one place was the committee able to find a standard set of practical instructions covering the points to be observed by the personnel of the engineering staff of the vessel in taking on oil or coal. Standard instructions are being printed and will be furnished to every vessel in glass-covered bulletin

*Prepared for the Marine Exposition, New York, November 11, 1922.
†Director of the Department of Maintenance and Repair, United States Shipping Board Emergency Fleet Corporation.

boards installed on the bulkheads in the mess-room of the engineers, so that there can be no question in future as to what the personnel of the ship should do to insure the highest quality and full quantity of fuel.

FUEL OIL BURNING SCHOOL ESTABLISHED

From the very outset of the committee's investigation it was apparent that as, in most of the other troubles of the merchant marine, the personnel of the ship constitutes at least 25 percent of the trouble. The men simply do not know the essential principles of economical burning of fuel. They have been operating so long under rule of thumb methods that the practice on board ship in our merchant marine is deplorable as compared with modern high-class power station practice. It was soon apparent that we would have to provide expert instruction for the engineers who were to be in charge of burning fuel, and this could best be done at the Naval Experimental Fuel Oil Burning Plant at Philadelphia. Our Navy has taken the leading part in the burning of oil fuel, and it is recognized everywhere abroad as having the greatest experience and the largest amount of expert technical data in connection with this problem, of any Navy or, indeed, of any engineering body of men. Thanks to the hearty co-operation of the Secretary of the Navy and Admiral J. K. Robison, arrangements have been made with the Navy to turn over this splendid experimental plant as a school of instruction for engineers of the merchant marine, and two classes have already been graduated from the school.

A more enthusiastic lot of men it will be hard to imagine than these classes are, both before and after going to school, and already the cry has gone up to provide for an additional so-called post-graduate course for many of these men, who see the great possibilities of saving that are possible under the expert teaching at the school. The classes are limited to from twelve to eighteen men and the instruction requires five full days of eight hours each, in which are combined lectures and practical work with boilers, burners and various instruments for determining the efficiency of combustion.

The managing operators have given the most hearty co-operation to this school, and the number of applicants is already greatly in excess of the ability to provide for so many eager engineers. The graduates of the school are already beginning to spread something of the doctrine obtained there and the practical ideas so new and interesting to them, and it is not too much to say that within the next year our merchant marine should have the best qualified set of fuel burning engineers of any in the world.

PRINTED INSTRUCTIONS ON PRACTICAL POINTS OF OPERATION

The committee has arranged to provide all chiefs and first assistants on our vessels with a set of pamphlet instructions containing the practical points of operation of all the various machinery in the engine department, including pumps, dynamos, ice-machines, etc. These are to be taken from a set of standard instructions that have been used with the greatest success in the Navy, and even before these are ready for printing and distribution the demand for them is so great that instead of printing by the hundreds we will have to have them printed by the thousands.

Indeed, the whole subject of conservation of fuel, and the millions of dollars that can be saved by intelligently burning it, has taken on new life and is being talked of more in engineering circles aboard ship than almost any other single thing.

The final work of the committee, after having prescribed how the fuel should be bought, how taken on board, and the standard to be met in burning the fuel, will be to take each and every vessel that cannot maintain the standard

set and place an expert engineer on board for a cruise to analyze carefully every phase of the operating and engine department with a view of bringing the vessel up to the standard set for it, and there is no doubt in the minds of the committee that within the next year or so there will be practically no vessel operating for the Shipping Board that is not maintaining a standard of fuel consumption equal to or better than that obtained either by our operators or by the vessels of our own country in private operation in either domestic or foreign trade.

MARKED INCREASE IN EFFICIENCY

The mere fact that an experienced committee of engineers is going to go over the records of the performance of the vessel has already resulted in a marked increase in the efficiency of the performance of many vessels. The good men are anxious to make their performance so good that their present performance will be quite equal to any standard that might be required of them; the inefficient men are afraid of losing jobs unless they can show a performance that measures up well to the standard, and the psychological effect alone of such a committee has already been found to be of the greatest possible help in bringing up the efficiency of the engine department, even though the committee did nothing along the more practical lines outlined above.

Largest Crane in the World at the Boston Army Base

The largest crane in the world, at the army base, South Boston, recently put in service, has a maximum capacity of 50 tons at radius of 90 feet. There are two auxiliary hoists with capacities of 15 and 5 tons at a radius of 130 and 133 feet, respectively. The crane without load weighs approximately 580 tons. This weight is distributed over 32 wheels, through a system of trucks which equalizes loads on the wheels. These wheels run on a 22-foot gage track. The trucks are so articulated that the crane will traverse the curve at the head of the dock, having a center line radius of 89 feet.

Electric Propelling Machinery of H. I. J. M. S. Kamoi

Propulsion Is by Synchronous Motors—Three-Bearing Construction Reduces Length and Weight of Turbine Generator

By W. L. Wright*

THE success of electric drive for merchant ships has again made itself manifest in the performance of the H. I. J. M. S. *Kamoi*, which has recently departed from this country on its maiden and home voyage to Japan. The *Kamoi*, which was built by the New York Shipbuilding Corporation at Camden, N. J., for the Imperial Japanese Navy, was launched on June 8, 1922, the official acceptance trials completed September 5 and 6, and she departed for Japan with cargo on October 5. Although to be operated by the Japanese Navy, she was built in accordance with Lloyd's requirements and carries a merchant ship classification.

This vessel is primarily a fuel oil tanker, length 496 feet, beam 67 feet, mean draft, loaded, 28 feet 9 inches, has a capacity for approximately 10,000 tons of fuel oil, and, in addition, has a bunker capacity for approximately 4,000 tons of coal. She is twin screw and designed for 15 knots speed at 8,000 shaft horsepower.

MAIN PROPELLING MACHINERY

The main propelling machinery, which is of the turbine electric type, was built by the General Electric Company and consists of the following:

1—General Electric Curtis turbine, 10-stage, 8,000 horsepower, 2,400 revolutions per minute, designed for normal steam condition of 250 pounds gage, 150 degrees F. superheat, and 1.5 inches absolute back pressure.

1—Main alternating current generator direct connected to above turbine, and rated 2-pole, 6,250 kilowatts, 2,300 volts, 3-phase.

2—Main propelling motors of the synchronous type, arranged for induction starting, each rated 40-pole, 3,125 kilowatts, 4,000 horsepower, 120 revolutions per minute, 2,300 volts, 3-phase, each direct connected to a propeller shaft.

2—400 kilowatt direct current turbine geared generators, arranged for condensing operation, each 5,000/1,100 revolutions per minute, 400 kilowatts, 6-pole, 225/112.5 volt, 3-wire. For supplying ship's light and power and excitation for main generator and motors.

1—Auxiliary alternating current generator, rated 2-pole, 625 kilowatts, 1,100 revolutions per minute, for emergency propulsion, arranged to be connected through a flexible coupling to the ar-

mature shaft of one of the auxiliary generating sets, the turbine and gear of which have an overload capacity for delivering 625 kilowatts continuous at the alternating current generator terminals.

1—Main control panel with high and low voltage control group for controlling the main generator and motors.

1—Direct current switchboard for controlling the 400 kilowatt auxiliary generating sets.

ARRANGEMENT OF PROPELLING MACHINERY

The arrangement of the propelling machinery is shown in Figs. 7, 8 and 9. It will be noted that the main turbine generator is located on a 28-foot flat, together with the two auxiliary generators, direct current switchboard, and main control panel; while the main motors and engine room auxiliaries are located in the space below. The arrangement of machinery in this vessel demonstrates the flexibility with which the electric system of propulsion may be installed as compared with other types of drives in which the prime movers are mechanically connected to the propeller shafts. The main generator, as located, is near the neutral axis of the ship and is thereby least affected by the rolling of the vessel in heavy seas. The foundation for the main turbine generator also serves as a support for the main condenser, which is connected to the turbine exhaust flange by means of a diaphragm type expansion joint. Two motor-driven condensate pumps of 120,000 pounds per hour capacity are located on the engine room floor directly beneath the main condenser. The main circulating pump of 15,000 gallons per minute capacity, which is also motor-driven, is located immediately forward and below the main condenser. The main condenser is equipped with two Le Blanc air ejectors.

AUXILIARY GENERATING PLANT

The port side of the 28-foot flat is devoted to the auxiliary generating plant consisting of two 400 kilowatt direct current turbine geared generators and the direct current switchboard. The auxiliary turbines are arranged to exhaust normally into the main condenser. However, an auxiliary condenser is provided for port use. Provision is also made for operating these sets non-condensing by opening a valve

* Marine Engineering Department, General Electric Company, Schenectady, N. Y.

Fig. 5.—Auxiliary Turbine Generator Supplying Ship's Lighting and Auxiliary Power

Fig. 6.—Direct Current Switchboard Controlling Ship's Light and Power Circuits

Figs. 7 and 8.—Elevation and Plan of Engine Room

to the auxiliary exhaust line. The excess steam above that required for feed heating and other purposes, when operating under this condition, is relieved to atmosphere through a spring loaded valve which automatically opens when the pressure in the auxiliary exhaust line rises above a predetermined value. The auxiliary condenser circulating and wet and dry air pumps are both steam driven.

The maximum lighting and power load of the vessel is such that only one set is required to operate at a time, thus always leaving one set in reserve. The alternating current auxiliary generator, which is used for propulsion in case the main turbine generator may become disabled, is arranged to be connected to the armature shaft of the outboard auxiliary generator. This is accomplished by means of a special flexible coupling which can be quickly engaged.

The direct current switchboard is located along the forward engine room bulkhead. This board consists of two generator panels and two lighting and power distribution panels. Provision is also made for supplying excitation for main generators and motors from this board.

On the starboard side of the 28-foot flat are located the ice machines, evaporators and machine shop.

MAIN CONTROL PANEL

The main control panel is located along the forward side of the engine room bulkhead, slightly to starboard on the same flat.

The contactor groups are suspended directly beneath the operating panel. The main cables connecting the main generators and propelling motors with the contactor groups are carried beneath the operating platform.

The main propelling motors are located in the engine room as far forward as possible in order to allow space for the turning gear, main thrust bearing and torsion meters and also to facilitate withdrawing the tail shaft without disturbing the main propelling motors.

VENTILATION OF GENERATOR AND MOTORS

Circulating air for dissipating the heat losses of the main generator and motors is taken from the engine room space. In case of the main generator the air is drawn through a suitable opening on the under side of the generator by means of fans built integral with the generator rotor. The air is forced through the air gap and passes out radially through suitable ducts built in the rotor punchings. The heated air is then forced through suitable ducts to the outside atmosphere.

In the case of the main propelling motors, the air from the engine room is drawn through screened openings in the end shields of the motor by means of a direct current motor-driven fan located just above and connected to the stator frame of the motor by suitable housing. The heated air is exhausted through a trunk which connects with the generator exhaust trunk and leads to the outside.

This arrangement of ventilation also aids greatly in ventilating the engine room by producing a constant change of air. Provision is also made for recirculating the heated air back into the engine room in case the temperature of incoming air is too low for the operating personnel.

The main propelling machinery as installed on this vessel, aside from the fact that special care has

Fig. 9.—Transverse Section Through Machinery Space at Frame 48, Looking Aft

been taken in design in order to produce apparatus that is well adapted for marine service in regard to accessibility, rugged construction and the use of high class insulating material for electric circuits, has several outstanding features that point to the rapid progress that is being made in the adoption of electric machinery for propulsion of ships.

FIRST TWIN SCREW VESSEL TO USE SYNCHRONOUS MOTORS

The *Kamoi* represents the first twin screw vessel to employ the use of synchronous motors. The first application of the synchronous motor for ship propulsion was successfully demonstrated on the S. S. *Cuba* in 1920, a single screw, 3,000 shaft horsepower express passenger ship. This was followed in 1921 by four 2,600 shaft horsepower single screw Coast Guard cutters. The success of the synchronous motor for this type of drive was made possible only after the amortisseur winding had been properly developed and applied in order to get the necessary torque characteristics, peculiar to ship propulsion, for starting and reversing.

MAIN TURBINE GENERATOR OF THREE-BEARING TYPE

The main turbine generator is the first marine set of its capacity to employ the three-bearing type of construction in which the generators and turbine rotors are connected by a rigid coupling and supported by one middle and two end bearings. This feature shortens the length of the set, and, therefore, decreases the weight and space occupied under that required for a four-bearing set of equivalent capacity.

NEW LONG RANGE MECHANICAL GOVERNOR

The main turbine is also equipped with a new type, long range mechanical governor, capable of holding the speed from 25 percent to 107 percent normal. The turbine speed is controlled by means of a hydraulically operated controlling valve located in the main steam line, which is actuated by means of a relay type pilot valve connected with the long range governor. The control of this governor is connected electrically with the main control panel, thereby giving the operator absolute control of the turbine speed for maneuvering the vessel.

In this type of drive, it is found desirable to do maneuvering which involves starting, stopping and reversing of the

motors at approximately 25 percent speed of the main generator. A limit switch has therefore been provided in connection with the control of the variable speed governor to open the control circuit when the setting of the governor is such as to maintain 25 percent speed. A limit switch has also been provided on the upper extreme, so adjusted that the speed maintained by the operating governor cannot rise appreciably above normal. By actual test, it has been found that the speed adjustment of this governor can be regulated from the full speed setting to 25 percent speed setting in approximately 12 seconds.

Two hand valves for controlling groups of first stage nozzles have been provided on the main turbine. These nozzles are arranged in groups of eleven, always open, five under one hand valve and three under the other. For economic, continuous operation, different combinations of nozzles may be selected to give desired speeds, in which case, the variable speed governor may be adjusted a few percent above that speed. In this condition, the operating valve, which is controlled by the mechanical governor, is in the wide open position and all unnecessary throttling from the

Fig. 10.—Propulsion Control Panel

main steam line to the turbine bowl is eliminated and the first stage nozzles will therefore be operated most efficiently. In case of heavy seas which result in wide variation of load, the turbine can only rise in speed until the operating governor comes into play. This automatically prevents the turbine from overspeeding. When the load is increased, the operating valve again opens, but the maximum steam flow is determined by the given nozzle setting. This resolves itself therefore into a constant steam flow condition, where the variable speed governor becomes a speed limiting governor. In this connection, it is obvious that a vessel with this type of speed control is able to maintain a higher average speed in rough seas than a type of control depending upon manually operated gear.

EMERGENCY GOVERNOR FITTED

The turbine is also equipped with an emergency governor which is mechanically connected with the main throttle valve and set to trip at 120 percent normal speed. This governor also has the dual function of relieving the oil pressure on the hydraulically operated controlling valve, thereby affording double protection in case of emergency. The controlling valve is also arranged to close and shut down the turbine in case of failure of the oil supply.

Gravity tanks have been installed in connection with the lubricating system, arranged with suitable valves, so that in case of failure of the lubricating oil supply, the main turbine bearings are supplied from the gravity tanks for a sufficient length of time to bring the turbine to rest.

CABLES

The terminals of the main generator are connected to the high voltage control group by two 1,250,000 circular mil cables per phase. The motors are connected with the high voltage control group by one 1,250,000 circular mil cables per phase. These cables are especially constructed for marine service, insulated with varnished cambric, reinforced rubber jacket and armored with phosphor bronze tape.

The high voltage control group consists of ten air brake contactors, so arranged that the motors may be cut in, out or reversed, at the will of the operator. The low voltage control group consists of eight air brake contactors arranged for controlling the excitation for the main generator and motors. Contactors of both groups are normally operated electrically by means of a controller located on the front of the operating panel. Manual levers, located adjacent to the operating panel, are provided for actuating the contactors in case of emergency. Mechanical interlocks are provided to prevent using both systems of control at the same time.

HOW THE SHIP IS OPERATED

The controller which is normally used for operating the ship consists of a selector handle for each motor, these handles each having three positions, "Off," "Ahead" and "Astern." There is also provided a field lever with four positions, "Off," "1," "2" and "Run." The motor selector handles are so interlocked with the field lever that they cannot be moved except when the field lever is in the "Off" position, which provides that no high voltage circuits can be interrupted under voltage. By means of the motor selector handle, the operator selects the condition of operation of the motors, "Ahead," "Stop" or "Astern." The operation actuates by means of solenoids, the contactors of the high voltage group and closes the proper circuits between the generator and motors.

The first position of the field lever actuates the main generator field contactors which closes the circuit of the 225 volt bus. This places double excitation on the main generator for starting, the motor field being open, the motors start as induction motors on the special squirrel cage winding. After the motors have reached a constant speed, the field

handle is moved to position No. 2. In this position, the contactors in the motor field circuit are connected to the 112 volt bus, giving normal excitation on the motors and double excitation on the generator. With this position, the motors pull into step instantly and the field handle is moved to the "Run" position. This places normal excitation on the main generator supplied from the 125 volt bus.

The field current of the main generator and motors may be adjusted independently or simultaneously by means of a hand wheel on the front of the operating panel, a clutch and gear mechanism being provided to connect the respective rheostat arms with the hand wheel.

INSTRUMENTS ON OPERATING PANEL

There are provided on the front of the operating panel, Fig. 10, the following instruments and meters by which the operator may observe at all times the exact status of operation:

- 1—Polyphase indicating wattmeter for determining output of main generator.
- 2—Direct current ammeters, one for each main propelling motor, arranged with selector switch to read current in all phases.
- 1—Alternating current voltmeter for main generator.
- 3—Direct current ammeters, one for each main generator and motor field.
- 1—Temperature indicator for main generator field.
- 1—Excitation indicator for determining the degree of excitation required for holding the motor in step.
- 1—Alternating current ammeter to determine flow of current to ground through generator neutral.
- 3—Speed indicators of the magneto type, one for each main generator and motor.

There are also provided two relays which are used in connection with the protective system which automatically opens the generator field contactors in case of abnormal unbalance of phases, or a ground on any part of the high voltage circuits including generator and motor windings.

TEMPERATURE DETECTORS

Temperature detectors are located in the armature windings of both main and auxiliary generators as well as the motors. The detectors are suitably imbedded in the slots adjacent to the coil by which the actual temperature of the coils may be determined. There are provided six detectors for each unit, same being connected to a suitable temperature detector panel, located near the control station. The temperature coils are so arranged that they may be connected separately to an instrument which indicates the temperature in degrees Centigrade.

New Conduit for Electric Wiring

THE American Wiremold Company, Hartford, Conn., has recently been introducing a new product, "Wiremold conduit," to naval architects and shipbuilders for concealing electric wires on the surface in cabins and staterooms. It is a rigid, thin wall tube made in three and four wire

Section of Wiremold Conduit

sizes and furnished in ten-foot lengths with couplings. The wires are fished in after the conduit and base plates of fittings have been secured in position.

This system is expressly designed to harmonize with joiner work, is finished in an attractive neutral tint and can be readily retinted to match other colors, thus avoiding conspicuousness. It is inexpensive, easily installed and has already been used on numerous small craft.

Sketch of 33-Knot Airplane Carrier Now Under Construction for the United States Navy

Powerful Airplane Carriers Building for U. S. Navy

Electrically-Driven Battle Cruisers *Saratoga* and *Lexington* Being Converted Into Floating Airplane Fields—Will Have Speed of 33 Knots

EVEN the group of electrically driven fighting vessels that includes the U. S. S. *Maryland*, the most powerful battleship in the world, will be excelled in propelling power, speed and length by the two airplane carriers which are now building for the United States Navy and which will be launched in about a year and a half. Originally, these two vessels were to have been the battle cruisers *Saratoga* and *Lexington*. The modification of America's naval program, due to the decisions reached at the Conference on the Limitation of Armament, led to the conversion of these battle cruisers into airplane carriers.

The Navy at present has but one airplane carrier, the U. S. S. *Langley*, which has just been commissioned and given its sea trials in Chesapeake Bay. The *Langley*, which is named after the scientist who made the first practical investigation of aeronautics, was rebuilt from the old collier *Jupiter*, the first vessel of the Navy to be equipped with the electric drive.

The two aircraft carriers being built from the battle cruisers will be literally floating airplane fields. They will also be floating electric generating plants. As naval vessels they will be the longest in the world.

MAIN PARTICULARS OF THE VESSELS

They will be capable of developing 180,000 horsepower, through four electrically driven shafts. This is almost six and a half times greater than the propelling power of the *Maryland*, representative of the Navy's present speediest class of capital ships, which is rated at 28,000 shaft horsepower.

The speed of the airplane carriers will be over 33 knots, or 12.6 knots more than the speed of the *Maryland*. Their length at the waterline will be 850 feet and they will have a beam of 105 feet. The *Maryland* is 600 feet long at the

waterline, with a beam of 97½ feet. The length of the *Langley* is 520 feet, and her beam is 65 feet.

The vessel which was to have been the battle cruiser *Saratoga* is building at the Camden, N. J., shipyard of the New York Shipbuilding Corporation, while the vessel originally designed as the *Lexington* is being constructed at the Fore River shipyard of the Bethlehem Shipbuilding Corporation at Quincy, Mass. The launchings of these ships, as airplane carriers, are expected in the summer of 1924.

PROPELLING MACHINERY

Continuing the policy first adopted in the case of the *New Mexico*, these vessels will both be electrically equipped throughout by the General Electric Company. The propelling machinery, designed with the utmost care by the engineers of the General Electric Company, and the same, barring minor alterations, as was planned for the original battle cruisers, will consist of four turbine generator sets, supplying current to eight electric motors in each vessel. The turbine generators will be operated by steam from sixteen oil-fired boilers and each will have a rating of 40,000 kv-a., 5,000 volts three-phase, 1,770 revolutions per minute.

The motors will be connected in pairs to each of the four propeller shafts. Each pair of motors will have an aggregate weight of 440,000 pounds. Each motor will have a capacity of 22,500 horsepower and will measure fifteen feet in diameter.

The total weight of the propulsion apparatus will be 2,100 tons. Each generator set will be about 40 feet in length and each pair of motors about 34 feet.

The work that is being done on the propulsion machinery for these two airplane carriers is being carried on under the direction of Admiral J. K. Robison, Chief of the Bureau of Engineering, U. S. N.

In addition to the propulsion machinery, each ship will be provided with six 750 kilowatt, direct current turbine generator sets, which will furnish direct current for all electrical purposes except main propulsion. Among other purposes to be served by this auxiliary generating equipment will be the operation of steering gear, anchor windlass, ventilation fans and lighting systems.

The airplane carriers will be among the first vessels of the Navy to embody the unique surface cooler system of ventilating their electrical machinery. This is a new application, developed by engineers of the General Electric Company originally for war ships, and now modified for use likewise in generating stations on land.

MACHINERY VENTILATING SYSTEM

On the aircraft carriers each of the four generators will have sixteen cooler sections and each of the eight motors will be provided with twelve, making a total of 160 cooler sections for the entire vessel. The coolers will make the electrical units entirely self-contained.

Formerly, a system of air ducts passed from the electrical machinery up through the hull of the vessel to the deck. Cooling air was drawn in through one set of ducts, and after passing over the electrical units and absorbing the heat, was sent out through another set. For vessels of 180,000 horsepower capacity, the duct openings would necessarily be numerous.

But the ducts are entirely eliminated by equipping each generator and motor with the radiators or coolers. These consist of a series of tubes through which water, pumped in from the sea, is circulated. The air that comes from the electrical machine is cooled by passing over the tubes, and the same air is then returned to the electrical apparatus, where it is again heated and again passed over the cooler, completing a cycle that is in continuous operation. The water in the cooler tubes, upon absorbing the heat from the air, is pumped out again into the sea. The elimination of the duct openings will result in vessels that are better protected from attack and are more seaworthy in storms.

RADIO EQUIPMENT

Like the *Langley*, these vessels will give particular attention to radio operations. Although to all appearance they will have decks that are almost unobstructed by masts and aerials, nevertheless, they will be completely fitted out for sending and receiving radio messages. Their aerials will be run to the deck from a single topmast, which can be lowered when necessary.

Below decks provision will be made for storing and maintaining a considerable number of airplanes and elevators and cranes will be installed with which to hoist them up from below, preparatory to hopping off from the flying deck. The flying decks will be unbroken except for a combination funnel enclosure, set off at one side of the hull.

Diesel Engined Tug Displaces Steam Craft

THE Abitibi Power and Paper Company, Ltd., Montreal, Canada, which operates a large paper mill at Iroquois Falls, Ontario, recently commissioned Ralph E. Winslow, naval architect, Atlantic, Mass., to design a new motor towboat to replace three steam towboats which the company formerly operated. The new tug, the *F. H. Anson*, is designed to tow booms of logs containing about 3,500 cords of wood for pulp wood from Couchiching Falls to Twin Falls, a distance of about twenty-two miles on the Abitibi river, Canada.

As it was expected that the tug would have to make a round trip each 24 hours, accommodations were provided for two crews as well as for extra raft men and company officials, although the tug itself could be operated by a crew of four men. As on this run the draft is unrestricted, the vessel was made deep enough to immerse a four-blade Columbian bronze propeller 6 feet 6 inches diameter by 4 feet 6 inches pitch. The principal dimensions of the tug are:

Length overall	83 feet
Length on waterline	77 feet 4 inches
Beam	20 feet
Draft	9 feet 6 inches
Shaft horsepower	300

The machinery equipment consists of a direct reversible 6-cylinder 12 15/16-inch by 18-inch Winton Diesel engine developing 300 brake horsepower at 210 revolutions per minute, a Winton auxiliary air compressor driven by a 12-horsepower motor, an Exeter bronze fuel oil transfer and service pump driven by a one horsepower motor, an Exeter fire, bilge and general service pump driven by a 5 horsepower motor and a 10-kilowatt Crocker-Wheeler electric generator driven by a 15 horsepower Frisbie engine. There is also a 25-cell 32-volt Edison storage battery and a 14-inch low-volted searchlight.

The hull was constructed in Northern Ontario under the supervision of the designer. The scantlings are in excess of Lloyd's requirements. The keel, frames, stem, stern frame,

etc., are of yellow pine and the ceiling and decks of Oregon pine. Three watertight bulkheads divide the hull into four watertight compartments. The fuel tanks hold 4,200 gallons.

Accommodations are provided for 12 men, six in the fore-castle, two in the engineer's stateroom, two in the captain's room and two in the company officials' room. In addition, there are the usual mess room, galley, storerooms, etc.

PERFORMANCE OF THE TUG

When running light the tug has a speed of 13 miles per hour. While towing rafts of logs about one-half mile long and about 800 feet wide the speed is 1 1/4 miles per hour.

Diesel Engined Tug F. H. Anson

The fuel consumption at 260 revolutions per minute, corresponding to 375 brake horsepower, is 24 gallons per hour; at 196 revolutions per minute, corresponding to 300 brake horsepower, 22 gallons per hour; and when towing at 176 revolutions per minute, corresponding to 287 brake horsepower, 18.5 gallons per hour. During the first six days of operation the tug delivered to the mill 14,500 cords of pulp wood, which the owners state is more than the three steam tugs, which the Diesel engined tug has replaced, could deliver in ten days' time.

Twin Screw Motor Passenger Liner Adda

Recent Motorship Building in Europe

New Motor Passenger Liner Adda Has Many Interesting Features—Danish Motorship Arizona Completes Her Trials

By Our Special London Correspondent

IN view of the fact that only a short time ago, an order was placed by the Union Steamship Company, of New Zealand, with the Fairfield Shipbuilding Company on the Clyde for the construction of a 20,000 ton motor passenger liner, the completion of the trials of the motorship *Adda* towards the end of November aroused a great deal of interest in shipping circles. The *Adda* is the finest and largest motor passenger liner that has yet been built, although she is not very different from the *Aba* (described in the January, 1922, issue of *MARINE ENGINEERING AND SHIPPING AGE*), which was placed in service a year ago.

The *Aba*, however, although holding the honor of being the first motor passenger liner in the world, was a converted cargo ship and is therefore perhaps not quite so fine an example of the shipbuilders' art as the *Adda*.

This vessel is to engage upon the regular mail and passenger service of the Elder Dempster Line between Liverpool and the West Coast of Africa, and is the finest ship now operating in that trade. She has a displacement 12,800 tons on a length of 450 feet. Her beam is 57 feet and her molded depth to the awning deck is 34 feet 6 inches. She is designed to maintain a speed of from 13 to 14 knots and has accommodations for 225 first, 74 second and 32 third class passengers.

From an engineering point of view, she is remarkable in many respects, quite apart from the adoption of internal combustion engines for propulsion. Coal has been entirely

eliminated, and electricity is used throughout for all auxiliary purposes, except for the main cooking range in the galley, and in this, oil fuel is utilized.

MAIN PROPELLING MACHINERY

The main engines consist of two of the standard Harland and Wolff sets, as built under license from Burmeister and Wain. They are eight-cylinder machines of normal type, developing 6,000 indicated horsepower at from 110 to 115 revolutions per minute, and they are similar in practically every particular to the motors which were built in the United States by the Wm. Cramp and Sons Ship and Engine Building Company and installed in the *Californian* and *Missourian*. In these large engines, however, it is found desirable to have two separate injection air compressors driven off the end of the crankshaft and arranged in tandem. This is a tacit recognition of the fact that the air compressor is now perhaps the most vulnerable part of a Diesel engine's equipment, and in the case of the engines of the *Adda* one of the compressors is sufficient to supply all the injection air necessary, so that, if there is a breakdown of an air compressor, the engine need not be stopped or even slowed down to any extent.

On trials these motors are found to have a fuel consumption of about 0.3 pound per indicated horsepower hour and the total amount of fuel required daily for the operation of the vessel, including that used for all auxiliary purposes, does not amount to more than 20 to 22 tons for a speed of

First Class Dining Saloon of Motorship Adda

about $13\frac{1}{2}$ knots. The diameter of the cylinders is 29.13 inches and the stroke is 45.28 inches.

STANDARDIZED AUXILIARY SYSTEM

Harland and Wolff, in the larger motorships which they have built for many British shipowning concerns, have standardized an auxiliary system, which, although apparently expensive, is almost ideal for the purpose. This arrangement is adopted in the *Adda* where there are four separate electric generating sets, arranged on the port side of the engine room in line. Each of these plants is driven by a three-cylinder four-cycle Diesel engine of 150 brake horsepower running at 300 revolutions per minute, the dynamo having an output of 100 kilowatts at 220 volts. The power is taken to a large switchboard mounted on a platform at the after end of the engine room and an interesting feature is the fact that the emergency lighting set which is installed in the steering gear house can be connected on to the main switchboard in the engine room to supply additional power if required.

The unusual plan has been adopted of having the emergency set an exact duplicate of the generating plants in the engine room, so that there are altogether five 100-kilowatt dynamos in the ship. This large plant is quite necessary, as may be imagined when it is stated that the motors are coupled up to the electric circuit and would, if all were operating at the same time, require between 800 and 900 kilowatts.

As is usual in Burmeister and Wain type equipment, all the auxiliaries required for the operation of the main engines are separately driven by electric motors. Unlike the American system, the cylinder jackets are cooled with salt water and the pistons with fresh water, separate electrically driven pumps in duplicate being provided for the circulation of the water.

The fresh water is passed through a cooler around which the sea water circulates before it enters the pistons. Lubricating oil is supplied from three small rotary pumps coupled to high speed electric motors and the bilge and general service pumps which are of the plunger type are also electrically driven.

AMPLE MANEUVERING POWER

British shipowners are very conservative in their ideas of the requirements of starting air for maneuvering purposes. As a result of this, as on many other British ships, a couple of large auxiliary maneuvering air compressors are installed, whereas in corresponding Scandinavian and American ships one is deemed sufficient. Each of these compressors, which is of the two-stage type delivering air at about 350 pounds per square inch, is driven by a motor of 180 horsepower and runs at 250 revolutions per minute.

The *Adda* carries 5,000 tons of cargo in addition to her passengers, and the cargo handling equipment comprises 12 electrically driven winches of the four-ton type. The controller for each individual winch is mounted on the top of the casting, but all the contactors and resistances are located in one large contactor house on deck. This is a usual system and although it occupies a good deal of space on account of the necessity of providing a large housing, it is found more satisfactory than the provision of a rheostat on each of the winches.

ACCOMMODATIONS

A feature of the accommodation is the number of single berth staterooms which are located on the bridge deck. These rooms are paneled in white and are furnished with a single bed of the cot type, a wardrobe and easy chair. On the awning deck there are two sets of suites each accommodating two passengers. Pullman berths are fitted in the suites and each has its private bath.

The double berth cabins are arranged on the tandem principle giving every room access to the ship's side. Each first class stateroom has a fresh water supply and basin with a special discharge which eliminates the necessity for a slop tank.

The second class cabins are unusually attractive to this class of travelers and are arranged in two- and four-berth rooms located on the main deck aft of the second class dining saloon. They are fitted with folding lavatories, wardrobes and the floors are covered with linoleum, with carpet and carpet runners.

VENTILATION

One of the most complete systems of forced ventilation has been installed so that the passenger in the privacy of his cabin may enjoy, with the aid of forced draft and fans, any

Second Class Smoking Room of Motorship Adda

First Class Cabin on Motorship Adda

Danish Motor Cargo Ship Arizona

particular degree of fresh breezes that he desires. There are 19 electrically driven Sirocco fans which are located on deck employed in the ventilation system and each cabin is supplied with individual fans under the control of the passengers.

SAFETY FEATURES

Twelve fully equipped lifeboats and a motor launch are installed which will take care of all on board in a case of emergency. These boats are handled by the Welin semi-rotary type of davit. Watertight doors below the main deck are electrically controlled from the bridge. Eight watertight bulkheads are fitted below the awning deck dividing the hold into seven spaces and above this deck steel bulkheads with fireproof doors divide the passenger accommodations into fireproof compartments. Chemical fire extinguishers are distributed throughout the passenger accommodations and a fire alarm system is installed that will immediately apprise the officer on watch of the location of any incipient blaze. Emergency power and light are secured by a 100-kilowatt dynamo installed on the awning deck which is capable of supplying all the essential services in cases of an emergency.

AN ELECTRICAL SHIP

Windlasses, cargo winches, steering gear, all engine room auxiliaries, fans, galley appliances and laundry appurtenances are driven by electric motors. Electric vapor radiators are installed in both passenger and crew space. These radiators are similar to the ordinary hot water or steam type except that the hot water is heated by an electric coil beneath each radiator. It is claimed that the loss of water is extremely small and that they are more economical than the central heating system, the average power required being about 1,000 watts.

REFRIGERATION

Insulated cargo and store spaces are fitted in No. 3 hold. Separate chambers are provided for poultry, meat, fish and fruit. The refrigerating machine was made by J. & E. Hall, Limited.

INTERESTING FEATURES

The hospital, which is located on the docking bridge, is

fitted with swing beds which counteract the rolling of the ship.

The laundry has been designed to take care of the passenger washing, a feature that will be appreciated by travelers.

In addition to the 12 electrically-driven cargo winches, a powerful warping winch with large drum ends has been

Assembly View of Engine of Motorship Arizona

installed which can be used as an emergency steering gear.

The scientific instruments used in navigating include a Clay automatic steering control which prevents errors in the execution of helm orders, pneumaticators for taking exact draft, tank gages in engine room to give direct readings of the fuel in the double bottoms, and long distance thermometers to give the temperature in the cold storage rooms.

Fuel oil is carried in the double bottom and in deep tanks aft of the motor rooms. She carries about 820 tons of oil which can be pumped aboard in about 5 hours and which is sufficient to enable her to make a round trip to West Africa and back without refilling.

MOTORSHIP ARIZONA GIVEN TRIAL

The motorship *Arizona*, which has recently completed a trial trip, was built by the Naskov Shipyard, Naskov, Denmark, for the United Shipping Company of Copenhagen. The principal dimensions and other particulars of the vessel are:

Type of ship	Cargo
Length between perpendiculars	405 feet 0 inches
Breadth, molded	54 feet 0 inches
Depth	36 feet 6 inches
Draft loaded	26 feet 0 inches
Deadweight capacity	9,100 tons
Stipulated normal average speed at sea	about 11 knots
Stipulated normal consumption of fuel oil per day	9 tons

MACHINERY

Type of machinery	Burmeister and Wain's 6 cylinder, 4 cycle Diesel engines
Number of main engines	2
Cylinder diameter	23.23 inches
Stroke	35.43 inches
Revolutions per minute	140
Indicated horsepower	2,800
Brake horsepower	2,200

The trial results over the measured mile in the Sound, on November 17, were:

Indicated horsepower, average.....	3,132
Revolutions per minute, average.....	144.5
Speed, average, knots	11.215

During the consumption test, the main engines developed 2873.6 indicated horsepower at 141.4 revolutions per minute, at a fuel oil consumption of 0.311 pound per indicated horsepower hour, net calorific value being 18,000 British thermal units, including the consumption of auxiliary engines producing the necessary current for the auxiliary machinery, steering engine and electric light.

The machinery is placed amidships and is of Burmeister and Wain's standard type for twin screw ships. The main engines are short stroke, forced lubricated crosshead engines, fitted on the front end with three-stage air compressors supplying the necessary injection air for atomizing the fuel oil.

All auxiliary machinery in the engine room as well as the deck machinery is electrically driven, the necessary current being supplied by three 50-kilowatt Diesel dynamos. The voltage of the current is 220 volts and for the lighting purpose it is transformed down to 110 volts by means of a motor generator.

Each of the generators is sufficient for supplying the necessary current under normal working conditions at sea, whereas two or all three generators have to be started, when the consumption of current is large, i. e., when maneuvering with the maneuvering compressor running or when loading or unloading the winches using much current.

The heating is effected by means of steam produced in a small cross tube boiler, this boiler also being able to deliver steam for fire extinguishing in holds.

The *Arizona* is the fourth motorship in the fleet of the United Shipping Company, Copenhagen, the other three motorships also being furnished with Diesel engines from Burmeister and Wain.

A Nesting Lifeboat With New Features

THE Balsa-Welin nesting lifeboat, manufactured by the American Balsa Company, Inc., Long Island City, N. Y., is a new nesting type boat which, as a result of holding sheer line and keel line parallel and rounding the bilges, can be nested closely together and readily launched.

The keel is built up of a flat outer keel, two angle bar keelsons and an apron plate between the keel and keelsons to which the shell plating is riveted.

The bottom shell is further strengthened by floors flanged to the shell plating and worked over the keelsons from bilge

Nesting Lifeboat

to bilge. These floors are also flanged at the top edge to take the footlings, thus giving a straight walking flat and allowing ample space between the shell and footlings to prevent the accumulation of dirt and rust.

The gunwales are of angle bar construction which increases the strength, durability and rigidity of the boat. As the drop leg of the angle bar is worked on the outside of the shell plating, moisture is excluded from the joint and the rusting away of the sheer strake is avoided.

The addition of floors flanged to the shell plating and the installation of angle bar gunwales have resulted in a boat so strong and rigid that in suspension tests the keel deflection is so little that it cannot be measured.

Germans Are Operating Large Motor Sailing Vessels

ACCORDING to a report recently received by the Department of Commerce, several German shipping companies have adopted the policy of building and operating large motor sailing vessels. In former times the installation of motors was restricted to small sailing vessels, but after the seizure of the German sea-going steamers by the allies it was decided that the quickest and least expensive way to increase the efficiency of the German merchant marine would be to install internal combustion engines on the large German sailing ships.

The quick journeys, especially to the West Coast of South America, which large German sailing vessels achieved before the war were remarkable, and the records of these ships were admired everywhere. A large part of their success is attributed to the Deutsche Seewarte (German Observatory), whose sailing manuals, monthly charts and other publications regarding sailing voyages have enabled commanders to choose the most advantageous routes for their trips and take advantage of favorable weather conditions.

The Deutsche Seewarte is also willing to train in a short time, and free of charge, captains and officers of vessels so that they will be able to judge meteorological conditions at sea. This knowledge is especially important to masters of motor sailing vessels in order that they may get the best results out of weather conditions. It will enable them to judge when it is best to use the sails alone, the motor alone or a combination of both.

General View of Simpson Dry Dock Plant, Looking Towards Main Ship Channel in Boston Harbor. In the Center Is the Power House and Pump Room, at the Right the 455-Foot Dry Dock, at the Left the 256-Foot Dry Dock (Unwatered)

Simpson's Patent Dry Dock Company of Boston Merged With Bethlehem Shipbuilding Corporation, Ltd.

THE recent acquisition of the plant of Simpson's Patent Dry Dock Company at East Boston, Mass., by the Bethlehem Shipbuilding Corporation, Ltd., marks another chapter in the history of one of the old ship repairing yards in New England. The history of this plant goes back to the days when the American clipper ships were carrying the American flag to all the ports of the world, and when American bottoms were carrying a large part of the commerce of the world.

The first dry dock, on Marginal street, East Boston, was built in 1853. Three years later the dry dock was purchased

by James Simpson, who established Simpson's Patent Dry Dock Company. Before the Civil War this dry dock was busy with repair work on clipper ships, and during the war much repair work on naval vessels was performed. It is said that the famous ship *Kearsarge*, after the engagement in which it put the Confederate commerce destroyer *Alabama* out of commission, came to this dry dock for repairs and was put into fighting trim.

Due to the growth of this business two other dry docks have been built, so that at present the docking facilities include one dock 455 feet long by 81 feet wide, one 256 feet long by 67 feet wide, and a small dock especially suited for tugs, fishing vessels and other small craft, 164 feet in length by 44 feet wide.

Equipment for doing repair work has been added to the plant as it has been developed. Recently a new power and pump house was built; also a well-equipped, modern machine shop. Other shops and equipment available for making all sorts of marine repairs include a boiler shop, paint shop, carpenter shop, blacksmith shop, derricks, etc.

Many well known vessels have been repaired at these docks. During the war a number of German vessels that had been injured by their crews after being interned were repaired here. Among these were the *Willehad*; the *Wittekind*; the *Ockenfels*; the *Iguassa*, a German boat interned in Rio de Janeiro and purchased by an American firm; and the *Don Juan de Austria*, once the private yacht of the Queen of Spain, now a United States Government boat.

This plant will be continued as a separate and complete repair yard by Bethlehem Shipbuilding Corporation, Ltd., and will be known as the Simpson Dry Dock Plant. S. W. Wakeman, general manager of the Fore River plant, has also been appointed general manager of the Simpson Dry Dock Plant.

The operation of this plant gives Bethlehem ship repair facilities centrally located in Boston Harbor, and in co-operation with the company's organization and equipment at Fore River, offers to the shipping industry means for complete service for ship repairing or shipbuilding.

Dry Docks of the Simpson Dry Dock Plant Looking Landward From Deck of Vessel. The 164-Foot Dry Dock is in Center, Between the 455-Foot Dock (at Left) and the 256-Foot Dock (Unwatered) at the Right

Largest Floating Dry Dock in the World Ordered

**All Steel Structure of Sectional Type 960 Feet Long
Will Be Able to Lift Vessel of 60,000 Tons Displacement**

SOUTHAMPTON, England, is to have the largest dry dock of its kind in the world. This dock, the plans of which are shown on the opposite page, will lift a vessel weighing 60,000 tons. As the docking weight of the *Majestic*, the largest ship in the world today, is only 52,000 tons, Southampton will be one of the few ports capable of docking any vessel that is likely to be built for some time to come.

The contract for the construction of the dock has been placed with Messrs. Sir W. G. Armstrong, Whitworth and Company, Ltd., Newcastle-on-Tyne, who will build it ac-

to list, it will be possible to correct it immediately by allowing some of the pumps to work faster than the others.

CENTRAL CONTROL

All of the pumps will be under the control of one man situated in the operating house on top of one of the wings. The valve operating mechanism and recording instruments will be installed in this house so that the operator will be able at all times to ascertain the true level of the dock and how deep she is below the water level at any particular point.

OTHER MACHINERY

The dock will also be equipped with many other appliances, including machinery for supplying compressed air, water pumps for fire service, and cleaning down, electric capstans for warping and hauling and traveling cranes for handling materials and equipment.

A site for the dock has already been selected and dredging operations have commenced. It will necessitate the deepest dredging ever performed, reaching to a depth of 75 feet at high water and 62 feet at low water. The amount of soil to be removed will aggregate 2,000,000 tons.

The dock will be placed quite near to one of the existing quays and two bridges will be provided by means of which the men engaged in repair work will be able to gain access to their work. A large floating crane is also contemplated which will be capable of lifting 75 tons by means of which heavy pieces of machinery can be placed aboard the vessel when she is in drydock.

Fig. 2.—End Elevation of 60,000-Ton Floating Dry Dock

cording to the plans of Messrs. Clark and Standfield, a firm of engineers that is responsible for the construction of many large floating docks in England and elsewhere.

CHARACTERISTICS

Length overall	960 feet 0 inches
Length over pontoons	856 feet 6 inches
Breadth of pontoons	170 feet 0 inches
Depth of pontoons	20 feet 6 inches
Depth of side walls	50 feet 0 inches
Depth overall	70 feet 6 inches
Length of side walls	756 feet 6 inches
Width of side walls at base	18 feet 6 inches
Width of side walls at top	12 feet 6 inches
Clear width of entrance	134 feet 0 inches
Height of keel blocks	4 feet 6 inches
Draft of water over keel blocks	38 feet 0 inches
Depth of water required at site	65 feet 0 inches
Lifting power	60,000 tons
Weight of steel, about	16,200 tons
Light weight of dock, about	18,000 tons

PUMPING MACHINERY DETAILS

Fourteen motor-driven centrifugal pumps will be installed having a total capacity of 20,000 tons of water per hour. A maximum of 80,000 tons of water will need to be ejected requiring 4 hours' time. Shore stations will supply the electricity to operate the pumps and other machinery.

One of the special features of the dock is the installation of 4 mechanical shores. By means of these shores a vessel entering the dock can be quickly centered over the keel blocks.

Another special feature is the arrangement that has been made to control the level of the dock while she is being pumped out. Each of the fourteen pumps will be placed in a separate watertight compartment and so, if the dock starts

Kendell Piston Rings

KENDELL piston rings which have recently been placed on the marine market by the Kendell Engineering Corporation, Fort Wayne, Ind., are of two-piece construction, an inner or expansion ring and an outer or packing

Two-Piece Piston Ring

ring. A special analysis iron is used, which after having been thoroughly seasoned is further improved by a special returning process on the expansion ring, producing what is termed an "even-radius" type ring, having equiradial expansion every 30 degrees on the

entire circle, all points having equal pressure. This is especially beneficial in slightly out-of-round cylinders. A non-clogging oil wiper is also provided in this section of the ring.

The outer or packing section of the ring is of softer non-resilient iron, being turned with an inner surface on a 55-degree angle, the expansion ring having an externally inclined face of the same angularity, thereby relieving groove pressure and increasing pressure on the circumference, lengthening the life of the expansion ring. This has also proven to be a non-carboning feature.

Relative Economy of Steam and Motor Vessels

Comparison of 10,000-Ton Steamship and Motorship for Voyages of 5,000 and 10,000 Miles

By Lawrence B. Chapman*

COMPARISONS of the steamship and motorship have been published from time to time but in nearly all cases the writers have attempted to prove the superiority of one type. Consequently the assumptions made and the figures used have always been favorable to one type and as a result the whole comparison has been biased and the conclusions reached untrue. Too often the comparison is made wholly on fuel costs and no allowance made for difference in cargo deadweight. In the following comparison the writer has no desire to prove the superiority of either type, his purpose being only to learn the truth regarding the motorship. Great care has been exercised in collecting the data, to make it as accurate as possible, and while certain assumptions have been made for the hypothetical case these favor neither type. As far as possible all data used have been obtained by sound scientific calculations.

MAIN PARTICULARS OF THE SHIPS

The ships chosen for the comparison are of exactly the same dimensions, namely:

Length between perpendiculars.....	420 feet
Beam	60 feet
Depth	35 feet 6 inches
Draft	26 feet

The block coefficient used is 0.78, giving each ship a load displacement of 14,600 tons. The sea speed is $11\frac{1}{2}$ knots and the net tonnage 4,750 tons. The steamship is fitted with a geared turbine, watertube boilers and uses fuel oil; the motorship is fitted with 2 four cycle engines.

The data for the ships are given in Table I, which has been taken with slight modification from the writer's book, "The Marine Power Plant."

The effective horsepower was carefully figured from Robertson's data and increased 10 percent for margin. In the motorship, which is twin screw, the effective horsepower was increased by 40 horsepower to allow for struts. The propeller revolutions per minute have been taken as 90 for the single screw geared turbine ship and 115 for the twin screw Diesel ship. These values represent present day practice. The propeller efficiencies were obtained from Taylor's charts using the revolutions per minute mentioned and wake values of 0.31 for the single screw ship and 0.23 for the twin screw ship. The propulsive coefficients were obtained by multiplying the propeller efficiency by the hull efficiency; the latter being 1.05 in the case of the steamship and 1.00 for the motorship.

The values used for steam pressure, superheat, vacuum and feed temperatures are given in the table. The steam per horsepower per hour is:

$$w_a = \frac{2545}{H_1 - H_2} \times \frac{1}{\text{efficiency ratio}}$$

$$= \frac{2545}{388 \times .63} = 10.40 \text{ pounds per shaft horsepower per hour}$$

Allowing 25 percent for auxiliaries, the total hourly steam consumption becomes 38,800 pounds. This allowance for auxiliaries assumes that the make-up feed is obtained by using an evaporator, hence only a small amount (2 percent) of feed water is carried.

FUEL CONSUMPTION

In order to obtain the fuel oil consumption of the steamship, a boiler efficiency of 90 percent of that obtained on tests was used to give the theoretical trial value. The theoretical trial fuel consumption for the motorship was taken as 0.42 pound per hour, which is the commonly accepted rate. As shown in Table II these theoretical trial fuel consumptions were increased 10 percent for the steamship and 5 percent for the motorship in order to get fuel consumption in service. While these percentage increases over trial conditions may be rather small for average service at sea, moderate increases over those used will affect the comparison very little, provided the percentage increase for the motorship is allowed as about half that of the steamship.

The weights given in the table were obtained from detailed calculations, the weights of the prime movers being obtained from the manufacturer in each case. The lengths of the machinery spaces are from detail layouts of main engines and all auxiliaries. The gross tonnage for each ship was the same, as the total double bottom was considered available for fuel oil. The machinery spaces in each case came above 13 percent; hence the net tonnage is the same for both ships. The weights and costs of machinery are for total machinery and include main and auxiliary generating sets.

TABLE I

	Steamship	Motorship
1. Model effective horsepower + 10 percent..	1,720	1,760
2. Number of screws (3 bladed).....	1	2
3. Propeller revolutions per minute.....	90	115
4. Propeller efficiency	0.550	0.605
5. Propulsive coefficient	0.577	0.605
6. Shaft horsepower	2,980	2,910
7. Boiler pressure (gage)	250	
8. Superheat (degrees F.)	100	
9. Vacuum (inches, mercury)	28½	
10. $H_1 - q_2$ (feed = 218 degrees)	1,079	
11. $H_1 - H_2$	388	
12. Efficiency ratio	0.63	
13. Steam used by main engines (pounds per shaft horsepower per hour)	10.40	
14. Auxiliary steam (percent of main engine) ..	25 percent	
15. Total steam per hour	38,800	
16. Boiler efficiency in service	72 percent	
17. Rate of combustion (pounds per square foot heating surface per hour).....	.55	
18. Fuel per shaft horsepower per hour (trial condition)	1.03	0.42
19. Total fuel per hour (no reserve)	3,080	1,220
20. Length of engine and boiler rooms (feet) ..	50	55
21. Total weight of machinery and boilers (wet), tons	400	755
22. Weight of machinery (pounds per shaft horsepower per hour)	300	580
23. Feed water for 5,000 miles (2 percent carried), tons	150	
24. Consumable stores, crew and effects, (5,000 miles), tons	50	50
25. Calculated fuel for 5,000 miles + 20 percent reserve, tons	750	300
26. Calculated fuel for 10,000 miles + 20 percent reserve, tons	1,500	600

WEIGHT

The weight of the hull and equipment for both ships is 4,200 tons. Table I gives the weights of the machinery. The gross deadweights thus become:

*Professor of Naval Architecture, Lehigh University, Bethlehem, Pa.

TABLE II.—ANNUAL OPERATING EXPENSES (Based on a cargo of 0.75 percent deadweight capacity)

	Steamship 5,000 Miles		Motorship 10,000 Miles	
1. Gross deadweight	10,000	9,645	10,000	9,645
2. Cargo deadweight (item 1—fuel, stores and water)....	9,050	9,295	8,100	8,945
3. Sea speed (knots)	11½	11½	11½	11½
4. Net tonnage	4,750	4,750	4,750	4,750

29. Annual operating expenses (sum 17 to 28).....	\$569,500	\$575,000	\$508,750	\$514,440
30. Rate per ton cargo to give 10 percent return on investment	7.28	7.30	11.70	10.90

*\$20,000 additional cost added because of electric deck machinery.

Gross deadweight of steamship=14,600 — (4200+400)=10,000 tons.
Gross deadweight of motorship=14,600—(4200+755)= 9,645 tons.

The net cargo deadweights are given in Table II.

Table II gives the summary of annual operating expenses and freight rates to give a profit of 10 percent on the investment for steamship and motorship for voyages of 5,000 and 10,000 miles. This table is based on an average cargo equal to 75 percent of the deadweight capacity in each case. While profit is in reality not an operating expense and most accountants today do not include interest on investment as an operating expense, it was thought best to arrange the work in this way in order to give the comparison on freight rates.

The calculated time at sea has been increased 5 percent to allow for bad weather and the calculated time in port for cargo handling has been increased 10 percent over that required to discharge and receive the cargo, to allow for tides, holidays and general delay. Thirty days per year have been allowed for docking, overhauling, painting, etc.

Table III gives the cost of crew together with their monthly wages. The wages have been kept the same for both ships. As a matter of fact, however, those for the motorship would be slightly higher as there would be two motormen per watch or one motorman and one electrician instead of one oiler and one fireman.

Fuel oil for the steamship has been assumed at \$1.50 a barrel and 8 pounds per gallon; Diesel oil has been assumed at 4½ cents per gallon (\$1.88 per barrel) and 7.35 pounds per gallon. Port fuel for heating, lighting and operating the winches has been taken as 7 tons per day for the steamship and one ton for the motorship.

TABLE III.—Crew's Monthly Wages (United States Shipping Board Scale, effective April, 1922).

Master	\$300

CALCULATIONS FOR STEAMSHIP

Calculations for the steamship on the 5,000 mile voyage follow:

8. Rate of stevedoring at 30 tons per hatch per hour =
$$30 \times 5 \text{ hatches} \times 10 \text{ hours} = 1,500 \text{ tons per day.}$$
9. Days on run = $\frac{11.5 \times 24}{9050 \text{ tons} \times 2 \times 0.75} \times 1.05 = 19 \text{ days.}$
10. Days in port = $\frac{1500}{365 - 30} \times 1.10 = 10 \text{ days}$
12. Single trips per year = $\frac{10 + 19}{11.53} = 11.53 \text{ trips.}$

16. Tons carried per year = $9050 \times 11.53 \times 75$ percent = 78,300 tons.
22. Fuel used at sea = $\frac{2980 \times 1.03 \times 19 \times 24}{2240} \times 1.10 = 688$ tons.
- Fuel used in port = $10 \times 7 = 70$
Total fuel per single trip, 758 tons
Cost of fuel per year = $758 \times 11.53 \times \$9.95 = \$87,000$
23. Lubricating oil, at 1 gallon per 10,000 shaft horsepower hours,
 $\frac{2980 \times 19 \times 24 \times 11.53}{10,000} = 1,570$ gallons per year.
- Cost of lubricating oil per year at 75 cents a gallon
= $1570 \times 0.75 = \$1,175$.
- Cost of feed water = $150 \times 11.53 \times \$1.00 = \$1,725$.
(Lubricating oil for the motorship was allowed for as 1 gallon per 3,000 shaft horsepower hours.)
26. Port charges:
- | | |
|------------------------------------|---------------|
| Pilotage (inward and outward)..... | \$273 |
| Towage (inward and outward)..... | 200 |
| Miscellaneous fees | 100 |
| Cooperage and dunnage | 300 |
| Clerks, watchmen, etc. | 200 |
| | <hr/> \$1,073 |
- Dockage at 2 cents per ton per day = $4,750 \times 11.53 \times 10 \times .02 = \$11,000$
- Tonnage dues at (6 cents and 34 cents $\times 4,750 \times 11.53 \times .20 = 11,000$
- Miscellaneous, (as above) = $1,073 \times 11.53 = 12,500$
- Port charges per year = \$34,500
28. Stevedoring of cargo = $78,300 \text{ tons} \times 2 \times \$0.70 = \$110,000$

CONCLUSION

The foregoing calculations which have been carried through in an impartial manner show that the steamship can carry cargo on the 5,000 mile voyage at \$7.28 per ton against \$7.30 per ton for the motorship. Thus there is a gain of 2 cents per ton in favor of the steamship.

A study of the main groups of operating expenses will clearly show why the motorship is at a disadvantage. All the groups are practically identical except group 21 (capital charges) and group 22 (fuel oil). While the motorship uses only 40 percent of the fuel that the steamship uses, the cost per gallon today is about 25 percent higher.

MOTORSHIP GAINS ON THE LONG VOYAGE

On the 10,000 mile voyage the motorship shows up decidedly superior to the steamship. For voyages greater than 10,000 miles there is no doubt that the motorship would prove its superiority over the steamship.

The foregoing comparison shows that the motorship is at a disadvantage because of the higher first cost. Twenty-five percent of this original cost appears in the annual operating expenses as capital charges (item 21). The capital charges for the motorship for both the 5,000 and 10,000 mile voyages are \$50,000 a year higher than the steamship, while the fuel costs for the motorship per year are only \$45,000 and \$50,000 less.

It would appear from the foregoing calculations that there is no gain in adopting the motorship for voyages less than 6,000 or 7,000 miles, unless the first cost of the Diesel engine can be reduced. This first cost will no doubt be reduced somewhat in the future due to standardization and increased experience. However, it hardly seems probable that the motorship will replace the steamship to any large extent until a cheaper design of Diesel engine is produced. The real solution in the opinion of the writer is the adoption of the two cycle engine. This will reduce the weight and consequently the cost of the engine, allowing the motorship to carry considerable more cargo than the steamship. This additional cargo together with cheaper fuel bill and lower capital charges will place the motorship ahead of the steamship even on short voyages.

If added experience allows the Diesel engine to use boiler fuel oil instead of the lighter Diesel oils, the operating costs of the motorship will be further reduced.

The machinery layouts clearly show that the Diesel machinery occupies slightly more space than the steam machinery although the general impression is that the motorship is superior to the steamship in this regard. With the adoption of the two cycle engine a considerable gain in cargo space will result.

Statements have often been made that the motorship carries more cargo per annum than the steamship but a study of Table II shows that for a 5,000 mile voyage the cargo carried per year is practically the same for the two types. This of course is due to the fact that the increased weight of the Diesel machinery (see items 21 and 22, Table I) more than offsets the reduction in fuel weight. On the 10,000 mile voyage the cargo carried by the motorship is considerably in excess of the steamship due to the lower fuel weight.

Table IV shows the operating expense groups arranged as percentages of the total annual operating expenses.

TABLE IV.—OPERATING EXPENSES

Operating Expenses	5,000 mile voyage		10,000 mile voyage	
	Steam-ship	Motor-ship	Steam-ship	Motor-ship
1. Capital charges (including profit)	44%	52%	49%	58½%
2. Fuel, lubricating oil and water	16	8	21½	11
3. Crew and subsistence.....	8	8	9	9
4. Brokerage and management	7	7	4½	4½
5. Port charges	6	6	4	4
6. Stevedoring of cargo	19	19	12	13
	100%	100%	100%	100%

Table IV clearly shows the relative importance of the items making up the operating expenses. Compared to capital charges and stevedoring, the fuel costs are relatively unimportant. It is seen that the Diesel engine loses out on the short voyage because of the large increase in group 1. This table is very significant in that it shows that the successful ship of the immediate future is not one in which fuel or crew wages are reduced so much as the one with the lower first cost and lower stevedoring charges. These last two items make up roughly 70 percent of the entire operating expenses—surely a field for searching investigation.

It is interesting to note in Table II that the annual operating expenses are less on the longer voyage than on the shorter voyage. This is due to the greater saving in cargo handling, which is practically cut in half on the longer voyage. The capital charges and fuel costs remain practically the same for both voyages. The Diesel wins out on the longer voyage because of the larger cargo carried, due to the reduced fuel and feed water weight and not because of the saving in fuel costs.

The figures and data used in the above comparison are for a hypothetical ship of 10,000 tons deadweight and of course do not apply to all cases. The figures do, however, represent general practice and small changes in any of the items will not affect the broad conclusion, namely, that a 10,000 ton motorship shows no gain over the steamship fitted with the most up-to-date power plant, for voyages under 6,000 miles. Changes in the size and speed of the ship will, of course, influence the result.

It may be that the repairs and maintenance charges for the motorship may eventually turn out to be lower than those of the steamship but until actual figures are available covering a period of years we are not warranted in favoring the motorship in the comparison.

EFFECT OF MODIFICATIONS IN THE DATA

If actual costs are available for Diesel machinery and fuel that differ from those used in the above comparison, modifications may be readily made in the table to get a com-

parison. Thus, for instance, if two cycle engines are available at a cost for total installations of \$380,000 and with a total machinery weight of 450 pounds per shaft horsepower the following changes will result:

Total cost of ship, \$720,000 + 380,000 =	\$1,100,000
Approximate increase in fuel and lubricating oil per year	\$4,000
Saving in capital charges per year	\$25,000
Saving in machinery weight	170 tons
Increase in cargo carried per year	1,500 tons
170 × 11.53 × .75 =	80,300 tons
Total cargo carried per year	80,300 tons
Annual operating expenses (\$575,000 — \$21,000)	\$554,000
Rate per ton	\$6.90

For the above conditions the motorship would be superior to the steamship on the 5,000 mile voyage.

If Diesel fuel can be purchased at a rate less than one and a quarter that of boiler fuel, the motorship and steamship will be nearly equal on the 5,000 mile voyage.

Further, if Scotch boilers are used in place of watertube boilers, the cost of the steamship will be slightly greater and the cargo carried per year about 900 tons less. This will be to the advantage of the motorship in the comparison.

Developments in the future, such as standardization, the adoption of the two cycle engine and the use of poorer grades of fuel in the Diesel engine, will reduce the length of voyage at which the steamship and motorship show the same annual operating costs. On the other hand, the adoption of Diesel machinery is bound to force those interested in steam machinery to improve the economy and efficiency of the steam plant, so that any gain to the advantage of the motorship is likely to be met by gains to the advantage of the steamship. In general, for ships of about 10,000 tons deadweight, the motorship will probably be largely adopted for voyages over 5,000 miles and for powers under 10,000 shaft horsepower, and the steamship for all voyages of 5,000 miles and less and for the fast and high powered ships.

It should be clearly borne in mind that the above comparison is for a 10,000 ton cargo ship on a given length of voyage at a speed of 11½ knots and the conclusions arrived at are for a specific case only.

New Steam Operated Reel for Use With Snubbing Wire on Canal Steamers

IN response to a demand for a steam operated reel for use with snubbing wire on canal steamers, the Montreal Drydocks and Ship Repairing Company, Ltd., Montreal, Can., has designed and successfully tried out the "Little Snubber" with engine attached, which is shown in the illustration. The reel is safe to operate and is not overpowered, being designed for operating from 40 to 180 pounds steam to

"Little Snubber" Steam Operated Reel

pull in the slack snubbing wire only. The reel can be operated by hand in single or double gear, if desired, without any change, and cable paid out on the brake.

A compact design of engine has been evolved which is easily overhauled and repaired, has large bearing surfaces and stows neatly away without taking up any more deck space than the ordinary hand reel. The whole outfit is relatively inexpensive and, if desired, the engine alone can be furnished for connecting to hand reels at little expense.

The gears are the only parts not of steel, and all shafts are square so that new gears can be slipped on as they come from the foundry and with no labor whatever in boring, keyseating, fitting, etc.

Concentration Salinity Indicator

THE newest development along the lines of the instantaneous determination of the chlorine content in a ship's water system has taken the form of a signal light controller. This apparatus, known as the Concentration Salinity Indicator, which is handled by The Babcock & Wilcox Company, New York, indicates automatically and instantaneously an increase in the density by showing various colored lights, a white light for 0.5 grain, a green light for 0.5 to 5 grains and a red light for a density over 5 grains. This is an especially valuable feature in connection with the evaporator room, as an instantaneous warning is given when the quality of the distillate changes, thus obviating the possibility of running considerable poor water.

The signal light controller also keeps a most accurate check on the condenser, which is an important feature for merchant vessels. A continuous indication of the quality of the condensate is shown at all times, the warning lights showing as in the case of the evaporator, but with a slightly different range. The white light shows a density up to 0.3 grain, the green light shows from 0.3 up to 1 grain, and the red light shows above 1 grain.

As a result of tests made on the United States battleship *Tennessee* for over a year under actual operating conditions,

Fig. 1.—Concentration Indicator and Selector Switch

the Concentration Salinity Indicator was installed on the battleships *Maryland* and *Nevada*, and subsequent to these installations the United States Navy has ordered complete sets for battleships, cruisers, scout cruisers and supply ships.

Indicators are also being installed

Fig. 2.—Signal Light Controller

on the S.S. *Leviathan* and on three New York City ferry boats.

Additional Views of Exhibits at the Marine Exposition, Grand Central Palace, New York, November 4-11, 1922

Ropes, Chains and Blocks for Shipbuilding Purposes—II

By Horace Holden Thayer*

Continuation of a series of articles containing information regarding shipbuilding materials and their uses that is not readily obtainable from shipbuilding handbooks and other generally available sources. The articles are not intended to be a complete exposition of the subject but will be found to contain items of value to the various classes of workers in this field who have to deal with these materials from the materials' point of view.

Davit guys and spans are preferably of wire rope, about $\frac{5}{8}$ -inch diameter. As no great flexibility is required, a 6 by 7 construction will suffice.

Lifeboat operating gear of vessels under the jurisdiction of the United States Steamboat Inspection Service has to meet with their approval.

DAVITS

Boat davit falls should be as flexible as possible. Where wire rope is used, this means the type of rope that will have maximum strength with minimum diameter and also a rope made up of fine individual wires. For ropes smaller than $\frac{1}{2}$ -inch a galvanized plow steel rope, of 8 by 19 construction, with ultimate strength about 90 percent of that given in Table IV, and of the diameter necessary to take care of the weight with a factor of safety of at least 5, is good practice. For ropes larger than $\frac{7}{16}$ -inch the 6 by 37 construction is desirable. Where the weights are moderate manila rope will answer.

Special shackles are required for boat davit blocks to take care of the connections at the davits and at the boats, with ample spread of jaw and ample distance between the base of the jaw and the center line of the pin. A swivel jaw shackle is desirable for the upper blocks and a regular jaw shackle for the lower blocks. Eight-inch double blocks are a good size for 3-inch circumference manila falls and 7-inch for $2\frac{1}{4}$ -inch circumference falls. Brass roller bushings are desirable.

EQUIPMENT

Anchor cables, stream lines, mooring lines and towlines, together with the anchors, form the so-called equipment of a vessel. Where a vessel is classed, all important particulars of the equipment are definitely specified by the classification society concerned and the cables are regularly tested by them. The equipment of such vessels has to be ordered in accordance with their requirements as to length, size, etc., and those who furnish it should be advised that it has to meet classification society approval.

The classification societies may be expected to approve for schooner barges and other craft that do not exactly come under their rules for steam or sailing vessels equipment that is in line with good practice even though it is not up to the standard determined by a strict application of their rules.

A good equipment is very important for the safety of the ship and all on board of her; and even where a vessel is not classed, classification society requirements should receive careful consideration in the selection of that equipment.

Wire rope equipment lines should be specified to be delivered on individual reels for each length, the reel being marked with the number of strands and wires per strand, the size of rope, the length of rope and the name of the manufacturer. All unworked ends of the ropes should have three servings or wrapping tightly applied.

The stream line should be of galvanized steel wire rope, preferably having 6 strands around a hemp center, with a hemp center and 24 wires to each strand. This may be

designated as the 6 by 24 construction with 7 hemp centers. It should have a galvanized hawser thimble spliced in one end. The strength should be in accordance with Table I.

The towline may be of wire rope or fiber rope. If the former on steamships and sailing vessels, it is preferably of the same nature as the above mentioned stream line, but with a galvanized hawser, thimble spliced in one end and a long spliced eye or loop in the other.

Wire rope towlines for seagoing barges are generally used in conjunction with towing engines and should have greater strength for their size than the 7 hemp center ropes so as to take up less space on the drums. For this service galvanized steel towing hawsers of 6 by 37 construction with one hemp center are preferable. A customary size is $1\frac{1}{4}$ -inch diameter and this size should have an ultimate strength of 108,000 pounds. It is desirable that such hawsers have a heart shaped cringle rove in the outboard end. They should be served back for 5 feet with galvanized annealed steel seizing wire. These lines are a part of the tugboat equipment. Fiber rope towlines for barges, which form a part of the barge equipment, are preferably of the strongest and highest grade manila because when a barge breaks adrift from its tow it is largely at the mercy of the elements. Bolt rope is therefore the rope to use. A 9-inch manila bolt rope towline should have a strength in excess of 65,000 pounds.

"Durable" wire rope towlines are of the 5 by 19 construction.

Wire rope hawsers, mooring lines and warps are preferably of the same construction as specified for stream lines, but having a long spliced eye or loop in one end. "Durable" wire rope hawsers are usually of the cable laid construction made up of five 5 by 7 ropes.

Chains should be in accordance with classification society requirements as to size, strength, size of links, etc. They should be coated with an approved protective covering. Anchor chain cables should be ordered complete with connecting and anchor shackles; and to insure that all connecting shackles will lead the same way over the windlass wildcat there should be an odd number of links in each length of chain. It is very important that the chain links and the wildcats match up. It is advisable to order with every suit of two anchor chains for ocean going vessels two spare anchor shackles and two spare connecting shackles complete and also two spare anchor shackle pins and four spare connecting shackle pins. All keeper pins in shackle pins should be of brass so that they may be readily renewed.

GANTLINES

Manila rope $1\frac{1}{2}$ -inch circumference will answer for this, with 6-inch single wood block with shackle to suit the connection and graphite bronze bushing.

HEAVING LINES

Ratline is used for this service.

LADDERS

Wire rope for ladders should be medium flexible and is preferably of 6 by 12 construction. Fiber ropes can be as specified under manropes.

* Member of the firm of Rossell & Thayer, naval architects and marine engineers, Philadelphia, Pa.

LANYARDS

The usual rope for this service is 4-strand tarred hemp rope.

LASHINGS

Lashings for spare propellers, anchors, etc., of considerable weight are preferably of flexible wire rope.

Fiber rope lashings for boats, small anchors, etc., and for general use about the vessel are preferably ratline.

Chains are used in some cases but are subject to excessive corrosion.

LEAD LINES

Lead lines are generally of cotton braided around a cotton center. They are smooth, flexible and have a polished surface. They are designated by a number which indicates the diameter in 32nds of an inch. The size is to suit the weight of the lead. For a 7 or 9 pound lead it may be No. 8, or 8/32-inch diameter, which runs about 44 feet to the pound and should have an average breaking strength of 300 pounds; for a 14 or 20 pound lead it may be No. 9, which runs about 36 feet to the pound and should have an average breaking strength of 400 pounds. For a 50 pound lead it may be No. 12, which runs about 20 feet to the pound and should have an average breaking strength of 700 pounds.

The Navy Department uses a braided cotton line 5/8-inch circumference for a boat's lead line, a braided flax line 1-inch circumference for a coasting lead line and a plain laid American hemp line 1 1/2-inch circumference for a deep sea lead line.

An untarred hemp line 3/4-inch circumference will answer for a hand lead line.

Hand lead lines are marked as follows, and should be well soaked before being marked:

- At 2 fathoms from the lead, with 2 strips of leather.
- At 3 fathoms from the lead, with 3 strips of leather.
- At 5 fathoms from the lead, with a white rag.
- At 7 fathoms from the lead, with a red rag.
- At 10 fathoms from the lead, with leather having a hole in it.
- At 13 fathoms from the lead, same as at 3.
- At 15 fathoms from the lead, same as at 5.
- At 17 fathoms from the lead, same as at 7.
- At 20 fathoms from the lead, with two knots.
- At 25 fathoms from the lead, with one knot.
- At 30 fathoms from the lead, with three knots.

The pieces of leather and rag as well as the pieces of cord in which the knots are to be tied for the 20, 25 and 30 fathom points should be securely attached to the line by a wrapping of waxed twine which is drawn through the cord once at the end.

The lead may be attached either by passing the line through the eye of the lead, knotting the line and securing the loose end by waxed cord, or, if the size of the eye permits, by making a long loop at the end of the line which can be threaded through the eye and passed over the end of the lead. Due allowance should be made, in securing the fathom markings, for the length of the lead and the methods of its attachment.

LIFEBOAT LINES

Lifeboats and life-rafts on all vessels under the jurisdiction of the United States Steamboat Inspection Service are required to be fitted with ropes as called for and approved by them. The painter for sea going vessel service has to be of manila rope not less than 2 3/4-inch circumference and of suitable length.

LIFE LINES

Lines for line carrying guns have to meet the approval of the United States Steamboat Inspection Service. They must be not less than 1,700 feet long and be capable of withstanding a breaking strain of 500 pounds. Life buoy lines are also subject to the same approval.

LIMBER CHAINS

Limber chains are usually 3/8-inch galvanized short link chains. A twisted link chain is preferable, and in large vessels a 7/16-inch chain is advisable.

LOG LINES

Log lines are the same as the cotton lead lines. The usual size is No. 8.

MANROPE

These are hand ropes and grab ropes of various kinds. A 6 by 19 galvanized wire rope is suitable. A good fiber rope for this service is the 4-strand tarred hemp rope, 2-inch or 2 1/4-inch circumference. It is frequently wormed, parcellled, covered with canvas and painted.

RAILINGS

Wire rope used as railings is preferably of the nature specified for awnings.

Chain used as railings in way of gangways, etc., or for portable railings around hatches can generally be 3/8-inch galvanized short link chain.

RATLINES

Ratlines are frequently made of iron; but where fiber rope is to be used this is the service for which ratline is particularly adapted.

RIGGING

The rigging on classed vessels is subject to classification society approval, and these societies have tabulated requirements for the standing rigging of sailing vessels.

The standing rigging does not require much flexibility and for sizes 1 1/2-inch diameter and less the 6 by 7 construction of wire rope is satisfactory. For greater diameters than 1 1/2-inch the 6 by 19 construction is preferable. It should be of galvanized cast steel with ultimate strength for the 6 by 7 rope as given in Table II, and for the 6 by 19 rope as given in Table III.

Wire rope running rigging should be as flexible as possible consistent with good wearing qualities. This calls for the use of the highest grade rope for such service as topping lifts, cargo hoists and davit falls, in order to keep the diameter as small as possible. The 8 by 19 plow steel rope is the most desirable and in the sizes required it should have an ultimate strength 90 percent of that given in Table IV for the 6 by 19 rope. Where it cannot be readily obtained the 6 by 19 rope of Table IV is suitable. For wireless halyards and similar service cast steel rope with an ultimate strength as given in Table V is satisfactory.

Running rigging is frequently galvanized although some of the manufacturers and users claim that the galvanizing is soon knocked off, leaving the rope in a worse condition than the ungalvanized rope. The writer is of the opinion that topping lifts should be galvanized and cargo hoists which are in frequent use not galvanized.

"Durable" wire rope for running rigging is of the 5 by 19 construction. It requires special sheaves and blocks.

Fiber rope for cargo operating is preferably a 4-strand manila rope with a heart, hard laid, and with tallow treated yarns. A special grade of manila rope is made for the running rigging of small boats, called yacht rope. The Navy Department recommends for the rapid handling of loads of about 900 pounds, such as coaling whips, a 4 1/2-inch circumference, 4-strand manila rope.

Fiber rope standing rigging is now practically obsolete except on small boats. A 4-strand tarred hemp rope is the type mainly used for this service. Running rigging is preferably the medium lay 3-strand manila.

A usual size for sails on steamships is 3-inch circumference for the sheets and halyards and 2 1/2-inch circumference for the downhauls. On large schooner rigged sailing vessels

								{ Wood 8"	12"	Double	Upset	With	Lower

(a) The becket is for a lashing.

(b) There is an additional 18 inch sheave in the end of the boom between the lower purchase block and the masthead block.

3 1/2-inch sheets, 3-inch halyards and 2 3/4-inch downhauls will usually answer for the jibs, and 4 1/2-inch sheets, 4-inch halyards and 3 1/2-inch downhauls for the principal sails.

When dealing with topping lifts it is well to bear in mind that they usually have to be handled over the gypsy head of the winch and also fastened around relatively small cleats. Wire rope is not so convenient to handle in such circumstances as fiber rope and the best arrangement is to have wire rope from the end of the boom to beyond the masthead block with a manila rope purchase from there on. There must be sufficient length of wire rope so that the end connection does not foul the masthead block when the boom is in its lowest position, and the lower block of the manila purchase has to be sufficiently low down to permit of the boom's being brought to the highest desired angle before the purchase blocks come block to block. Complete manila topping lifts are subject to undesirable stretch.

It has been customary with a number of the east coast naval architects and shipbuilders to use 1/2-inch plow steel rope for cargo whips on the ordinary run of freighters. This is flexible and therefore easy to handle and amply strong for the usual service. In many cases, however, stevedores on the west coast have refused to unload vessels thus equipped, demanding 5/8-inch hoisting ropes. The writer knows of one vessel in particular which met with this demand and not being able to obtain the 5/8-inch rope was obliged to fit out with a set of 3/4-inch cargo hoists before the cargo could be discharged. This is a point to be borne in mind in cases where the 1/2-inch rope appears to meet the requirements of the service.

Vang pendants should be about two-thirds the length of the boom.

Chain in rigging is met with principally in parts of the running rigging and the bowsprit shrouds of sailing vessels, and for the Burton sling method of cargo handling and cargo slings generally. The former are determined by classification society requirements, and the "Coil" grade of chain is frequently used. The latter are referred to under the head of slings. Chains are also used as topping lifts where booms attached to king posts or ventilators are not raised or lowered when in operation. In some cases a section of chain is attached to the end of the topping lift, with long links that

can be conveniently hooked over some anchorage, to hold the boom in the desired position.

Blocks are an item of considerable interest in connection with the rigging. The bushings should in all cases be of a good quality, such as self-lubricating graphite bronze. Cargo hoist blocks are preferably Metaline bushed. Where ropes passing over the blocks have a considerable change of direction in the course of their operation, care should be taken to select blocks that will permit this without fouling distance pieces or other parts of the blocks.

Table VIII gives in a concise manner data for the rigging of cargo masts and booms, representative of good practice, showing the approved materials and sizes, the relations between ropes and blocks, and other information. The 1 to 5 ton layout covers a pole mast with two shrouds port and starboard; and the topping lift is a one part wire rope with a manila purchase as before explained. The 30 ton layout covers a pole mast with one preventer stay, port and starboard, and three shrouds, port and starboard.

SEIZING

This, as its name implies, is a fastening and generally means the fastening together of parts of larger ropes such as anchor lashings, boat gripes, etc. The seizing rope before described is used for this. Tarred marline is also used for small seizing.

SERVING

The process of covering a rope with a smaller rope tightly wound around it is called serving. The rope is first generally wormed and then parcelled as later explained.

Tarred marline, houseline, roundline, hambroline and spun yarn are used for this. The last mentioned is preferable as it lies smooth under the serving mallet and makes a close fitting watertight covering. Ratline is used for heavy serving.

SIGNAL HALYARDS

Manila rope 1 1/8-inch circumference is frequently used for these on steamships, with 4-inch single wood blocks with regular shackles and graphite bronze bushings. Untarred hemp rope will answer, and on smaller vessels may be 1-inch or 3/4-inch circumference.

SLINGS

Wire rope slings of various kinds are preferably of the 6 by 37 construction. For cargo handling they are usually of 1-inch wire 30 feet long with a thimble in each end. Boat slings and slings of small diameter rope can be of the 8 by 19 construction.

Fiber rope slings are preferably of three strand common lay manila.

Chain slings are of galvanized short link chain. As made up for Burton slings for cargo handling they are preferably two 10-foot lengths of the highest grade short link chain connected by a ring at one end which takes the cargo hook and with a swivel and shackle at each of the other ends. A good size is 1-inch with a 4-inch inside diameter ring, 1 1/4-inch swivels and 1 1/8-inch shackles. Ordinary cargo slings are double and can be bought in any desired length with a ring at one end and hooks at the other. Standard lengths are 10 feet and standard sizes are 1-inch, 3/4-inch and 1/2-inch; all of the highest grade short link chain, galvanized.

STACK GUYS

Stack guys can be of galvanized cast steel wire rope, 6 by 7 construction, with ultimate strength as given in Table II. A suitable size for stacks as met with on the ordinary run of cargo steamships is 3/4-inch. They can also be of galvanized wire strand made up of 7 or 19 wires twisted together, the latter being used for the larger sizes.

Stack guys can also be of galvanized short link chain.

STEERING GEAR

Steering gear ropes require great flexibility, particularly where they are required to pass around drums or sheaves. The 6 by 37 construction of wire rope is often used, being of plow steel for transmission ropes and cast steel for tiller ropes. A special construction for this purpose consists of six small ropes around a hemp center, each rope being of the 6 by 7 construction with its own hemp center. These ropes can be obtained from 1/4-inch to 1-inch diameter.

The last mentioned rope, 3/8-inch diameter, is sometimes used for steam steering engine controls but stretches too much for such service. The regular 6 by 19 cast steel rope is satisfactory for these controls.

Bronze tiller ropes are used considerably on small vessels, and also braided cotton ropes with bronze or steel wire cord centers.

Fiber ropes are preferably 4-strand or 6-strand with heart, hard laid, and with tallow treated yarns. The 6-strand rope is the more flexible and better for work on steering wheel drums of small diameter.

Chain for steering leads is mainly used around the steering engine drum and in way of the quadrant, and is preferably the highest grade of short link chain. Rapid wear takes place in way of the sheaves. Backing chains are also short link chains.

Guide sheaves should fit the ropes or chains and be of ample size.

STORES

Stores, deck outfit, etc., for the ordinary run of cargo steamships should include about

- 120 fathoms of 1 1/8-inch circumference manila—3 strand.
- 120 fathoms of 1 1/2-inch circumference manila—3 strand.
- 120 fathoms of 2-inch circumference manila—3 strand.
- 240 fathoms of 2 1/4-inch circumference manila—3 strand.
- 480 fathoms of 2 1/2-inch circumference manila—3 strand.
- 480 fathoms of 3-inch circumference manila—3 strand.
- 2 coils of 9 thread manila—200 fathoms.
- 1 coil of 15 thread manila—200 fathoms.
- 20 pounds of 3-yarn spun yarn.
- 1,500 feet of plow steel wire rope of the size and construction used for cargo hoists, as spares.
- 1 chain sling 10 feet long—1-inch chain.
- 4 chain sling 10 feet long—3/4-inch chain.

1 chain sling 10 feet long—1/2-inch chain.

2 wire slings 30 feet long—1-inch wire, with thimbles in ends.

Spare anchor shackles as mentioned under equipment.

Blocks for stores should generally include the following, together with other spare blocks and sheaves that will meet the requirements of the particular service:

Purpose	No.	Size	Type	Hook	Becket	Bushing
Lead gear	2	8-inch	wood-double	loose	with	graphite-bronze
Lead gear	2	8-inch	wood-double	loose	without	graphite-bronze
Lead gear	2	10-inch	steel-snatch	swivel	without	graphite-bronze
Lead gear	1	8-inch	wood-snatch	swivel	without	graphite-bronze
Hoisting gear..	2	16-inch	steel-double	loose	with	metalline
Hoisting gear..	2	16-inch	steel-single	loose	with	metalline
Hoisting gear..	2	14-inch	steel-double	loose	with	metalline
Hoisting gear..	2	14-inch	steel-single	loose	with	metalline
Watch tackle..	2	8-inch	wood-double	swivel	with	graphite-bronze
Watch tackle..	2	6-inch	wood-double	swivel	with	graphite-bronze
Relieving tackle	4	8-inch	wood-double	swivel	with	graphite-bronze

WIRELESS HALYARDS

Wireless halyards, if of wire rope, are frequently made 3/8-inch diameter, even where a smaller rope would answer as far as strength is concerned. They are preferably galvanized cast steel 6 by 19 construction, with ultimate strength as given in Table V.

Manila ropes should be of ample size to take the load.

Blocks for wire rope can be of small size on account of the practically permanent nature of the installation.

WORMING

Worming is the process of winding small ropes or "fittings" along the grooves between the strands of a wire or fiber rope that is to be parcelled with canvas or other cloth thereby making a more even surface for the cloth covering. Tarrred marline or seizing is used for wire ropes, and marline, seizing, houseline, roundline or hambroline are used for fiber ropes. The size to use depends upon the size of the groove to be filled in.

MISCELLANEOUS

The following points are of interest in connection with a consideration of ropes:

Turnbuckles are preferably of the pipe variety where exposed to the weather so that the threads will be protected as much as possible from corrosion; although on sailing vessels where shrouds have to be disconnected so that cargo grabs will clear them, open turnbuckles are sometimes more easily handled.

Wire rope sockets have proved their worth as substitutes for thimbles and splices, and when properly applied will not pull loose even when the rope is pulled to destruction. The wires are spread apart in the form of a brush inside of the socket, which is then entirely filled with pure molten zinc. In order to guard against corrosion of the rope from water around it where it enters the socket, the rope should be wormed, parcelled and served for a length of about two feet, the parceling and serving extending on to the socket for about two-thirds of its length. The closed sockets are the most desirable for the rigging and similar work.

Lightning conductors might be considered under the head of wire ropes. They are of course of copper. A good size is the 1/2-inch rope composed of 34 No. 15 B.W.G. wires.

Air Gun Has Wide Range of Usefulness

JENKINS BROS., Bridgeport, Conn., manufacturers of air valves, have produced a new type air gun which has a wide application in foundries, machine shops, wood working mills and the like for cleaning chips, dust and foreign matter from work being fabricated and from molds and castings. A special feature of this gun is a renewable disk designed for air service which forms a perfect contact on the valve seat and takes up the wear of frequent usage. The gun can be used with 1/8-inch, 1/4-inch, 3/8-inch and 1/2-inch hose pipe by the use of different size nipples.

New System Removes Oil Sludge and Dangerous Gases

H. J. Wheeler Salvage Company Perfects Nozzle Which
With Aid of Vacuum Pump Emulsifies Oil Residue

By Gunnar C. Engstrand, M.E., B.A.*

A NEW system for removing and disposing of the oil sludge or residue that accumulates in the double bottoms and tanks of oil burning vessels has been evolved and put into operation in New York harbor by the H. J. Wheeler Salvage Company of Brooklyn, N. Y. As is well known, this residue which is a thick clinging mass of almost jelly-like consistency is very unpleasant and difficult to handle.

It is heavier than oil and settles on the bottoms of the tanks. Sometimes it is heavier than water in which case, if discharged overboard, it would sink harmless to the bottom but more often it is about of the same specific gravity of water and it remains suspended in the form of chunks, threads or flakes. It is in this condition that it is particularly dangerous, for when it is washed against a solid, like piles or bulkheads, it will tenaciously cling to their surfaces which in a short time receive a tar-like inflammable coating.

It is claimed that because this oily residue has about the same specific gravity as water a satisfactory separation by centrifugal means cannot be obtained and that the mixture removed by such means is not suitable or fit to be burned under boilers. In fact it must be disposed of as a dangerous waste, as obnoxious and inflammable gases generate from and cling to the sticky surface of the residue.

ARRANGEMENT AND METHOD OF OPERATION

The arrangement of the Wheeler system is shown in Fig. 1, where a section is taken through the salvaging barge and a vessel from which oil sludge is being removed. Starting

Fig. 1.—Section Through Salvaging Barge and Vessel from Which Sludge Is Being Removed

in the oil tank and attached to a flexible hose is a nozzle, the mechanical arrangement of which has not been made public. The nozzle is globular in shape, having air inlet holes spaced circumferentially around it. A tubular extension of several inches projects beneath it.

It will be noted that there are two tanks on the deck of the barge with an air pump placed between them and it will also be seen that these tanks discharge to the hold of the barge, to tanks ashore or to a tender alongside.

The system operates as follows: The intake of the nozzle is immersed in the sludge to be removed but not deep enough to submerge the air inlet holes in the globular body. Using a working vacuum of only 20 inches, air from the atmosphere is drawn through the inlets with a velocity of approximately

800 feet per second and in so doing mechanically cracks the oily residue until it is minutely subdivided and suspended in the moving air stream inside the hose. In other words, the sludge which is as heavy or heavier than water is emulsified and drawn up through the flexible hose and into one of the cylindrical tanks shown. When one of the cylindrical tanks is filled the suction is by-passed to the other tank, while the discharge from the full tank to the hold of the barge is opened and the emulsified oil blown into it. The contents of the tanks can also be discharged to receptacles on shore or to a tender alongside by means of compressed air.

Fig. 2.—Wheeler Barge in Operation

After this emulsified product has settled in the hold of the barge the oil will flow to the surface leaving clear water underneath.

The bottom settling is clean water which is discharged overboard and the oil residue, which is now free of water, is suitable for burning under the boilers.

A very important claim for this system is that the obnoxious and dangerous gases that are generated in oil tanks are pumped out with the air and sludge. Chemists' tests have shown only a trace of .001 vapor in tanks after cleaning with the Wheeler apparatus.

Hundreds of well-performed tank cleaning jobs in the port of New York have amply proven the efficiency of this apparatus. Even "sour" oil which is an intimate and churned mixture of oil and water will separate. This separation takes about 12 hours, while the settling ordinarily is effected in 3 hours.

Fig. 2 shows one of the Wheeler barges in actual operation alongside of a ship. A striking example of the low specific gravity of the emulsified residue was shown on a recent job on the *American Legion*. One of the Wheeler barges named the *Gladiator* pumped 150 tons of oil residue from the forepeak of the *American Legion* in 44 hours against a head of 65 feet. The importance of the ability to carry a hose up over the high deck of a passenger ship and remove such a substance as oil sludge against a head of 65 feet does not need any comment.

*Chief engineer, Donnelly Dry Dock Company, Inc., New York.

Twin-Screw Oil Burning Turbine Liner *Albert Ballin*

New System of Anti-Rolling Tanks Installed—To Equal *Majestic* and *Leviathan* in Comfort and Conveniences

ACCORDING to cable advices received from the Hamburg-American Line in Hamburg, their new twin screw oil burning turbine steamship, *Albert Ballin*, was successfully launched in the yards of the Blohm and Voss Shipbuilding Company of Hamburg on December 16, 1922.

The *Albert Ballin*, named after the late Director General of the Hamburg-American Line, is the first one of two large steamers of modern type ordered by the company about two years ago for the service between Hamburg and New York

occur on account of shallow draft as in the case of the *Cap Polonio*.

ACCOMMODATIONS

Accommodations have been provided for 250 first class passengers. In the planning and equipment of the state-rooms and suites the greatest care has been exercised to make them equal in comfort and convenience to the gigantic *Imperator* and *Vaterland*, which were put in service by the Hamburg-American Line just before the war. There will be four large suites consisting of sitting room, bedroom and bath as well as wardrobe or trunk room, and a number of large staterooms with private bath. All of the other cabins will be of large size and comfortably arranged. There will be only a small number of inside rooms, and even these are so placed that they will receive light from the side ports. All rooms will be equipped with regular beds, wardrobe, dressing table, and most of them with running hot and cold water. Liberal space has been provided for the public rooms such as social hall, library, writing room, smoking room with gallery and veranda café, gymnasium and electric bath.

The main promenade deck, partially enclosed with "Laycock" windows, as well as the boat deck, will provide ample space for deck chairs and promenading.

The second cabin, accommodating 340 passengers in large well-ventilated 2- and 4-berth rooms, will have very commodious and well-appointed public rooms, *i. e.*, social hall, smoking room and large dining room, the latter with a capacity for 300 persons at one sitting. Also in the second cabin the stateroom arrangement has been so planned that there will be only a few inside rooms. There will also be ample space for deck games and promenading.

Passenger elevators are provided for second cabin, as well as first. Particular attention has been given to the location,

Fig. 1.—Old Type Anti-Rolling Tanks

via Southampton and Cherbourg. The sister ship *Deutschland* will be launched from the same yard in the course of 1923.

The vessel just launched is scheduled to enter the joint service maintained by the United American Lines and the Hamburg-American Line in May, 1923. The *Albert Ballin* is a vessel of 22,000 tons gross register. She is over 600 feet long overall, with a beam of 73 feet, and is provided with 7 decks for the accommodations of 250 first cabin passengers, 340 second cabin passengers and 1,100 third class passengers.

FRAHM ANTI-ROLLING TANKS

A special feature of this new ship will be a new anti-rolling tank system which is an invention of Dr. Frahm of the Blohm and Voss Shipbuilding Company. This is the first application to a steamship of the new system which is a combination of the built-in tanks ordinarily employed, see Fig. 1, and the hull bulge, see Fig. 2, which was originally tried out as an experiment in the construction of the steamship *Cap Polonio*.

The *Cap Polonio* was built especially for the South American service and required light draft in order to be able to navigate the comparatively shallow waters of the River Plate. In order to insure stability on this light draft, bulges were incorporated on each side of the hull along a considerable length and this experiment has proven quite satisfactory in stabilizing the ship. Dr. Frahm then conceived the idea of combining the anti-rolling tank and the bulges which has been successfully applied to submarines. In the case of the *Albert Ballin* and the *Deutschland* the bulge plan has been adopted in order to give stability above the ordinary rather than to overcome instability that might

Fig. 2.—Showing Bulge Anti-Rolling Tanks

arrangement, and equipment of the kitchens, pantries, storerooms and refrigerator rooms for the large quantities of food supplies required, so as to furnish the best possible service and cuisine.

The third class, which is provided with a large and tastefully appointed social hall, smoking room and dining room, the latter with a capacity for 420 passengers, will have state-

room accommodations for 660 passengers in 2-, 4- and 6-berth rooms. Additional space for about 440 third class passengers in large and well-ventilated compartments for families can be arranged for, if necessary.

For the safety of the passengers and crew adequate life boats are provided, suspended from the latest approved type of davits. A powerful wireless station is located on the uppermost deck of the ship. The hull is divided into numerous watertight compartments which can be controlled from the captain's bridge. In addition there will be provided all modern safety devices, such as smoke detecting apparatus (Rich system) for fire prevention, submarine bell system,

Fig. 3.—Steamship Albert Ballin Recently Launched at Hamburg

telephone connections to all departments of the ship, gyroscopic compasses, automatic steering device, etc., etc.

The engine room is equipped with steam driven turbines with double reduction gears, which will develop 13,000 horsepower, giving the vessel an average speed across the Atlantic of 15½ knots. The 8 large Scotch boilers are fed with fuel oil and equipped with Howden's forced draft. The oil is carried in specially built oil bunkers, as well as in the double bottom, which are provided with every known safety device.

System for Handling Bunker Oil From Storage

A SYSTEM of fuel treatment which supplies a practical method of handling lower grades of fuel oil from storage is being manufactured by Row and Davis Engineers, Inc., New York, under the name of the RanD system. This system, it is claimed, reduces the cost of upkeep and costly delay in handling fuel oil by avoiding the use of steam heating coils in the inner bottom tanks. In the RanD system circulation is maintained in every part of the tank by means of a jet of heated oil forced into the mass of cold oil. This jet of hot oil comes from a discharge nozzle shown in Fig. 2, which is so constructed that it revolves slowly in a horizontal plane, thereby causing agitation in every direction throughout the tank.

The supply of hot oil comes from a central heater located in the boiler or engine room with connection to a circulating pump which, in ships already constructed, is generally the existing transfer pump.

If the vessel is not fitted with a supply or settling tank, a specially designed bulkhead connection is fitted with frames and covers to which is attached a heating coil with outside

joints and an auxiliary suction valve to the deep tank. This forms an auxiliary for temporary use after the vessel

Fig. 1.—RanD System of Handling Lower Grades of Fuel Oil

has been lying at its dock and the entire mass of oil in the deep tank has become congealed. The discharge from the circulating pump is led to the central heater where the

Fig. 2.—Revolving Discharge Nozzle

oil is heated by exhaust or live steam. It then goes to a main discharge pipe with distributing branches leading to the discharge nozzles of each tank compartment.

CONSOLIDATION OF WAR AND NAVY DEPARTMENTS PROPOSED.—Consolidation of the War and Navy departments into a Department of National Defense, designed to function under a Cabinet officer with assistants in charge of the army and navy, respectively, has been definitely recommended to President Harding by Walter F. Brown, head of the commission appointed to prepare a plan of government reorganization. The President has recently been giving a good deal of time to the consideration of the entire report and is expected to send a special message to Congress on it soon.

Questions and Answers Relating to Naval Architecture and Marine Engineering

Conducted by James L. Bates, Naval Architect, and W. B. Newton, Marine Engineer

This department is maintained for the purpose of answering all questions relating to ships and their machinery. All inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

Stop Waters

Q. (1176).—What are stop waters and where are they used?

A. (1176).—Stop waters are strips of tarred hemp felt, flat lampwick or burlap, soaked in a mixture of red and white lead, or sometimes a stiff mixture of red and white lead putty. They are placed between joints where watertightness cannot be obtained by calking and also where non-watertight members pass through watertight members to prevent water passing from one side of the watertight member to the other.

See page 461 "The Naval Artificer's Manual," by Pate.

How to Remove Dent from Shell Plating

Q. (1177).—Please describe means or method of removing a dent from a vessel's plating.

A. (1177).—When the dent is not deep it is sometimes possible to remove it by hammers or jacks. If the dent is deep, a hole may be drilled in the center and a draw bolt introduced. This bolt extends through a heavy strong back placed on the concave side of the dent. As the bolt is drawn up, hammers should be used on the convex side. Under some circumstances the plate must be heated at the dent by means of a blow torch.

Outlook for Naval Architects

Q. (1181).—What do you think is the outlook in the marine engineers' and naval architects' profession for the near future? I have just graduated from a first class technical university. I feel that I cannot afford to lose much time and follow up a line which may continue to have poor prospects for new entrants for some time to come.

A. (1181).—The outlook in the marine field today, so far as that portion of it which touches and competes with foreigners is concerned, is very uncertain. We have not been a maritime nation and we do not yet really know what the attitude of the American public is toward our foreign going merchant marine.

I believe that we as a nation must ultimately, in self-defense, develop and support a foreign going merchant marine. It will probably be a matter of education and development. Such a course may be a matter of years, perhaps decades.

There is and has been for years business on the Great Lakes and along our coasts. This business has gradually built up large fleets of ships of special types.

I look for a great, possibly gradual, expansion in traffic on our inland waterways. There has been much experimental work along this line in the past ten years. This work is already showing results.

If a young man is thoroughly trained for and interested in marine work, I think he will be able to make a fair living at it, particularly if he connects himself with concerns which

deal largely in shipping for the Great Lakes, inland waterways or coast and gulf.

However, I have known a number of young men of good education and excellent ability who have left the marine field and made good in business or other branches of engineering. I believe that they have in most cases secured greater and more immediate returns than would have been theirs had they remained in the marine field.

Finest Form of Underbody

Q. (1183).—Kindly advise me as to the finest form of underbody which can be used. I am anxious to obtain a form of very low resistance and understand that destroyers are sometimes given block coefficients of 0.39 and 0.40.

A. (1183).—The block coefficient is not considered a good criterion for underbody form when speed is the governing consideration because it gives no satisfactory idea of the longitudinal distribution of displacement. It is important to have this latter information because at moderate speeds

$$V$$

(values of $\frac{V}{\sqrt{L}}$ less than 1.1 to 1.2) the forward portion of the hull does the greater part of the wave making while at high speeds (those above $\frac{V}{\sqrt{L}} = 1.1$ to 1.2) the whole body

takes part in wave making. Now a small longitudinal coefficient means a concentration of displacement amidships; that is, a large midship section and finer ends. A large longitudinal coefficient means displacement distributed toward the ends or a moderate midship section and relatively full ends. Hence, for vessels of moderate or slow speeds in which low resistance is a governing factor a low value of the longitudinal coefficient is desirable. In vessels of high speed a high value of the longitudinal coefficient is used.

You have given no idea of the type of vessel or the speed which you have in mind. The following figures taken from successful vessels may prove of value:

	No. 1	No. 2
Length	510 feet	289 feet
Beam	63 feet	26.1 feet
Draft	20.5 feet	8.3 feet
Displacement, tons	10,000	742
Block coefficient	0.53	0.415
Midship section coefficient	0.98	0.67
Longitudinal coefficient	0.54	0.62
Designed speed—knots	23	30
$\frac{V}{\sqrt{L}}$		
Values of speed-length ratio, $\frac{V}{\sqrt{L}}$	1.015	1.76

No. 1 is a fuller vessel than No. 2 when judged by the block coefficient, but as shown by the longitudinal or prismatic coefficient it is a finer ended vessel.

The speed-length ratio for No. 1 is much lower than that for No. 2. The values of the longitudinal coefficients are suited to these speed-length ratios.

The *Shipbuilding Cyclopaedia*, Basic Design Section, gives data for the selection of suitable values of longitudinal coefficient for varying values of the speed-length ratio.

NEW BOOKS

Notes and Calculations on Marine Propulsion and PracticeReviewed by **H. Bakewell-Taylor***

THE MARINE POWER PLANT. By Lawrence B. Chapman, Professor of Naval Architecture, Lehigh University. Size, $5\frac{3}{4}$ by $9\frac{1}{4}$ inches. Pages, 320. Illustrations, 113. Tables, 15. New York, 1922. McGraw-Hill Book Company, Inc. Power Plant Series.

This book represents in printed form a series of lectures given by Professor Chapman to the marine engineering students of Lehigh University. The chapters are well written and possess the great commendation of brevity without loss of substance and necessary facts.

The little volume, while being intended for the elementary classes in marine engineering, contains much information in a compact form to make it useful as a reference book to marine engineers, draftsmen and superintendent engineers, and it could be studied with much advantage by the sea-going engineers of our merchant marine desiring a fuller knowledge of certain facts and figures connected with their profession as well as by operators who wish a closer grasp of marine engine practice and progress. While not as large and detailed a work as the well known volumes of Seaton, Durand and Bauer, nor along the more specific lines of those by Dyson, Peabody, Barnaby and Bragg, the book is nevertheless a distinct addition to the all too scarce well arranged and up-to-date literature on marine engineering design, principles and practice.

The chapters are clearly written and well illustrated and the text, other than simple and necessary equations and formulæ, has been kept particularly free from involved mathematics, the author giving, however, some very useful curves and tables as well as a number of fully worked out examples in marine power plant design and also some general arrangement of machinery drawings.

The book includes chapters on Thermodynamics of Steam, Fuels, Marine Boilers, Combustion, Draft, Superheaters, Reciprocating Engines, Turbines and Gears, Combination Machinery, Steam and Diesel Electric Drives, Diesel Engines, Condensers, Air Pumps and Feed Heaters, Power Plant Layouts, Computations for the Power Plant of the Merchant Ship, together with a chapter on Comparison of Coal and Fuel Oil for Steamships. The author has confined himself to stating the broad principles of each subject dealt with in the various chapters of the work, and has conservatively analyzed and presented the conclusions drawn therefrom. While ship-resistance, propellers and detailed engine design are only briefly touched upon, readers are referred to authoritative works on these and kindred subjects.

The tables and data given cover Machinery Weights per Horsepower, Steam and Fuel Consumption per Horsepower, Steam Consumption of Marine Auxiliaries, Reduction Gears, Condenser Performance, Comparison of Machinery Installations, Diesel Engine Trials, Diesel and Electric Drive Ship Particulars, Performance of Steam Reciprocating Engines, Particulars of Fuels, etc., etc. The worked out calculations and examples for proposed designs of propelling machinery are clearly presented, and the general data in the text are for the most part up to date and reliable in so far as they could be referred to in the limited time given to a preliminary study of the volume.

*Chief Turbine Engineer and Chief Inspector for United States Shipping Board, New York.

We would suggest that in a future edition the chapters be a little more logically arranged in engineering sequence, and that certain illustrations be placed with the text of the chapters they are to illustrate, particularly those of the Howden Forced Draft System shown on pages 84 and 85; also certain similar figures should be numbered "a" and "b" so as to conform to the practice followed elsewhere in the volume, and Fig. 60, showing the General Electric Company's type of Geared Turbine, which has evidently been accidentally omitted, should be included.

In conclusion, the author is to be complimented on turning out a handy, lucid and excellent little volume which should add to the series it is written for and be on the bookshelves of marine engineers, naval architects and operators, in addition to providing the students for whom the lectures were prepared a permanent printed record of them.

LETTERS TO THE EDITOR

A Proposed Remedy for Vibrations Caused by the Propeller

A POINT that is frequently overlooked in propeller design is the tendency of the wheel to produce vibrations. To be sure, these are often caused by disturbances which are outside of the province of the designer, such as unequal pitch, which may be due to warping of the blades or poor workmanship when the blades for a built-up propeller are assembled. These, however, are probably of a small magnitude in comparison with the one con-

Fig. 1

trolled by the designer, namely the distribution of the blade area.

Fig. 1 shows roughly the waterlines of a single screw ship with a propeller of the conventional right handed type. In order to explain the action of this propeller in a simple way we shall refer to a propeller pump with guide vanes. When these guide vanes are pointed in the direction of rotation a minimum discharge is obtained, whereas if the guide vanes are pointed in the opposite direction, or against the rotation, it is a well known fact that the discharge will be a maximum.

Referring to Fig. 1, it is shown that the ship's lines resemble very closely the guide vanes of a propeller pump, at least to an extent sufficient to invite a discussion. If we study a blade as it approaches the top, we find that at first, when it is horizontal, feed is normal, then as the blade moves

closer to the top a reduced feed is experienced because the lines of the ship follow the direction of rotation. The feed reaches a minimum when the blade is about to pass the sternpost, and it is therefore obvious that, as less work is performed, the torque will also reach a minimum. In ships that have a heavy deadwood and have the propeller working in close proximity to this, very severe vibrations are encountered; the dangers of this kind of construction are, however, generally realized.

It might be argued that in a ship with a very fine run this tendency for vibration should be obviated, but it must be remembered that in this case the whole stern structure will respond more readily to any disturbance.

When the leading edge of the blade has passed the sternpost, the ship's lines are inclined against the direction of rotation and the feed, and consequently the torque, will, therefore, tend towards a maximum. Where the angle of the run is large this change will naturally cause an increase in the fluctuations. As the blade moves on, the stream lines following the sides of the ship and the wake acting on the back side of the blade cause the torque to reach a maximum. This cycle will of course be repeated as many times per revolution as there are number of blades per propeller and thereby produce vibrations. The same discussion also applies to the lower side, although in most cases to a less degree.

The obvious remedy for this trouble would of course be to have the propeller removed as far as possible from any influence of the ship, an attempt to which is found in the rake of the blades. This, however, is not sufficient and we must

Fig. 2

Fig. 3

therefore look for another remedy. Figs. 2 and 3 show two blades with extremely different outlines. The leading edge of Fig. 2 is straight in a radial direction, whereas Fig. 3 has a gradually curved leading edge. If we now apply the above discussion to these blades, we find that the entire length of the leading edge shown in Fig. 2 will enter the region of maximum feed very suddenly and the change from minimum to maximum torque will therefore be almost instantaneous. The curved edge of the other blade, Fig. 3, will on the other hand change from minimum to maximum conditions very gradually and the fluctuations will be very diminished. If special attention were paid to this feature when designing a new propeller, it would be almost possible to build a propeller having no vibrations. This kind of blade would also perform much better when the propeller is only partly submerged.

It must of course be admitted that a blade of this type, having the maximum blade area near the hub, is not quite as efficient as a blade of standard shape but all engineering is of necessity a compromise to arrive at the best average results.

Fig. 3 is an approximate outline of the type of propeller which replaced the original wheels on a well known quad-

ruple screw turbine steamer. It is probable that vibrations were partly responsible for this change, because any reduction in propeller efficiency caused by the overlapping blades would probably not be tolerated in an installation of this size unless it were absolutely necessary. The stress at the root of the blade could not have been the only cause, because the added metal which increases the blade area at this point has practically no influence on strength.

From a purely economic point of view, it should undoubtedly prove beneficial to pay close attention to this subject of distribution of blade area and shape of the leading edge, inasmuch as it results in a smoother working of the entire installation and thereby reduces the maintenance cost.

Kingfield, Me.

HAROLD ANDERSON.

Why the Poughkeepsie Did Not Make Her Speed

The *Poughkeepsie*, which was recently placed in operation on the Hudson river between Poughkeepsie and Highland, N. Y., is the first ferryboat to be constructed on the "Hullfin" principle. She is 140 feet in overall length, 52 feet in extreme beam and has a loaded draft of 9 feet 6 inches.

The main part of the hull is broad and shallow, having no overhanging ends or guards. It is built of steel and designed with the extra strength necessary to permit its use as an ice breaker in unusually heavy ice. On the bottom of the hull a fin is constructed that is six feet wide and six feet deep amidships. This fin is made just wide enough to allow for the installation and care of the electric propulsion motors and tapers in width to the stem and stern posts which are placed about 20 feet back from the ends of the hull.

The propelling machinery consists of two six-cylinder Diesel engines of 150 horsepower each, which are directly connected to two 90 kilowatt generators which in turn were supposed to actuate two electric motors of 100 horsepower each at 600 revolutions per minute. This ferryboat was intended to make 10 miles per hour with this minimum power plant and would have done so, but right after a permit to use the "Hullfin" patents had been obtained the inventor was not allowed to co-operate in the construction of the vessel and many parts of the hull were built in direct opposition to his advice.

The following are my reasons why the ferryboat did not make her intended speed: First, the fin was built two feet deeper than was necessary or intended, creating quite an unnecessary drag.

Second, although a 3½-inch propeller shaft was considered ample by the machinery people for the size of the wheels and the power applied, a 5-inch shaft was used, wasting much power.

Third, the stern posts of the fin and the fore-and-aft edges of the rudders were unnecessarily thick, which greatly disturbed the water in the vicinity of the high-speed propellers.

Fourth, the propellers were found to be much larger than the motors could turn. The design called for 600 revolutions per minute, but only 350 could be obtained, which gave returns equivalent to half speed and power. The only way to obtain the full efficiency from the power in this craft is to design the propellers with a smaller diameter and less pitch, and with edges properly shaped for the high revolutions.

Fifth, the bow of the fin is located well aft of the bow of the main part of the hull where the bottom is wide. The forward wheel drives the water faster as it spreads along the wedge shaped side of the fin and when this water arrives at

the widest part of the fin it is going at such a high rate of speed that it is unable to change its course quickly enough to follow the lines of the fin. Thus there is a void formed which holds on to the boat until the suction is relieved by water, as there is no opportunity for air to get there. By experimenting this suction was discovered and by the same means a remedy was found which is known as the air release. This is a means of allowing air to be drawn through holes in the skin of the vessel in the proper places to relieve the suction.

In closing, I will state that it is only necessary to reduce the size of the propellers properly, and to apply the air-release, to get fair results from the power applied. Much better results might have been obtained if all material parts had been produced with the proper degree of fineness to obtain the best results from the small amount of power.

New York.

SAMUEL GOLDEN, President,
Hullfin Boat Company.

Why More Power Can Be Obtained by Solid Injection

With the solid injection system that we use, very high net mean effective pressures, figured from the brake horsepower, are obtained. With the ordinary air injection system it is very difficult to get over 80 pounds mean *net* pressure per square inch, while with the solid injection we are able to get very high mean net effectives, in some cases running as high as 135 pounds, and even slightly higher. We rate our engines at 100 pounds, at which mean net effective pressure there is perfect combustion, the height of thermal efficiency and therefore a clear exhaust.

There are three principal reasons why higher mean net effective pressures can be obtained with a solid injection. The first is the elimination of the power necessary to drive the high pressure air compressor supplying air for injection purposes. In engines of small size, it takes an average of 10 percent of the main power to drive this compressor, which is entirely saved with the solid injection. In addition to this the high pressure air expanding in the combustion chamber from 1,000 pounds to approximately 500 pounds absorbs a great deal of heat from the compressed air in the combustion chamber. This heat has been obtained at the expense of power in compressing the air in the combustion chamber. This loss of heat decreases the pressure in the combustion chamber, resulting in the loss of just that much power, which we find, by experiment and careful analysis, to be about 8 percent. It is true that the indicator card, with the air injection system, does not show any drop of pressure at the top of the working stroke; on the contrary, there is a slight raise in pressure, which is approximately five pounds, this pressure being maintained for a slight distance across the card as the piston is on the downward stroke. This loss makes a total of 18 percent, which is saved by the use of solid injection, and therefore adds that much to the mean net pressures.

In contrast with this operation of the high pressure air injection, we have the solid injection engine injecting the fuel into the combustion chamber without the thermal loss from the high pressure air, as explained above. No heat is lost from the compressed charge of air, consequently a lower compression (about 350 pounds) is equally effective in igniting the fuel. As the fuel enters through the nozzle into the combustion chamber, there is a sharp rise in pressure, which takes place at the top dead center on the working stroke and amounts to from 200 to 250 pounds. The fuel continues to enter over approximately the same length of stroke as the air injection engines (about 30 degrees), and this higher pressure, which we call the maximum work-

ing pressure, totaling approximately 550 pounds, is held over quite a period on the downward working stroke of the piston, thus greatly increasing the area of the indicator card, resulting in a much higher mean net effective pressure.

It is true that the mean indicated pressures of the air injection engines are nearly as high as those on the solid injection. No doubt they would be the same, if it were not for the thermal losses from the expanding high pressure air, because the mechanical losses are about the same in each type, except that which is accounted for in the high pressure air compressor.

The extremely high mean effective pressures which can be obtained from solid injection are due, so far as we are able to ascertain, from what the refining companies call the cracking process. Our theory of this matter is very well borne out by an analysis of the exhaust gases and from a knowledge of the characteristics of oil under similar conditions. We explain it in the following manner:

Oil is made up of little cells, which we may consider for the moment as being circular and similar to a grape, with an outside skin composed of the lower carbons, while the interior contains the higher volatile hydrogens, and also probably contains a slight pocket of gas of some form. When oil is put under a high pressure (1,000—4,000), as it is for solid injection, it compresses slightly. It is very probable that this compression is allowed by the small gas pocket contained within the cells of the oil. When these cells escape quickly from their high pressure in the nozzle they expand quickly to their natural shape and, assisted by the heat in the combustion chamber, they burst, thus releasing the hydrogen, or, as some term it, freeing the carbon. The hydrogen burns, or rather unites more readily with the oxygen than does the carbon, and generates a good deal more heat per each unit of H_2O than per unit of CO and CO_2 . By releasing an excessive amount of oil in a combustion chamber it appears that the hydrogen burns first to a large extent, thus greatly increasing the heat and power, as long as there is oxygen left for it to unite with, and leaving the carbon in the form of gas still unburned and which is driven out through the exhaust on the scavenging stroke. This, of course, is not good economy, and consequently we rate our engines at a low enough mean effective pressure, to give the height of thermal efficiency and fuel economy. This is about 100 pounds per square inch.

The rise in pressure at the top of a working stroke, by the use of solid injection is sometimes called detonation and can be well considered as such except that it is not the kind of detonation experienced in a gas engine, where it is more or less objectionable, owing to the inability of controlling the point of pre-ignition, which causes the detonation in the gas engine. With a Diesel engine the point of ignition is absolutely controlled by the timing of the valve, thus getting power from these detonations, and still having a soft, smooth running engine, very similar to a steam engine which always has a certain amount of lead, as well as lap, to cushion the impulse over the center.

Oakland, Cal.

O. A. TREIBER,
Atlas Imperial Engine Company.

THE AMERICAN ENGINEERING STANDARDS COMMITTEE has approved as "Tentative American Standard" the methods for the chemical analysis of alloys of lead, tin, antimony and copper—otherwise known as babbitt metal—submitted by the American Society for Testing Materials. Two methods of analysis are included in the document approved by the A.E.S.C. The first is a quick and fairly accurate method intended for practical or shop use; the second is a slower, more elaborate and more expensive, and more exact method intended for reference purposes or for the settlement of disputed questions.

PERSONAL MENTION

G. F. S. MANN has become connected with the estimating department of the Charles Ward Engineering Works, Charleston, W. Va.

A. J. PASCH has been appointed head of the South American and West Indian trades for the Shipping Board, effective January 15, vice S. W. Pierce, resigned.

JOSEPH T. MARTIN is now engaged in business at Baltimore, Md., as a consulting engineer and marine surveyor with offices at 409 Exchange Place.

FREDERICK FRANZ, who for the past four years has been chief engineer of the Terminal Engineering Company, manufacturers of industrial trucks for marine terminals and the like, has established an engineering office at 27 Warren street, New York City.

MICHAEL D. SCHAEFER, who has been the civilian aid to the chief constructor, U. S. Navy, for many years, has resigned from the service to engage in private business with Commander J. W. Barnett, Jr. Mr. Schaefer probably knows personally more people in the marine field than any one else connected with the industry and his genial personality certainly entitles him to the best wishes of all his friends in the new venture. It is understood that Messrs. Schaefer and Barnett will specialize on Diesel engines, motorships and submarines and that they will also act as agents in Washington, D. C., for the Marine Decking and Supply Company and the Huhn Manufacturing Company.

Michael D. Schaefer

G. T. BRADLEY, formerly traffic manager for the United States Shipping Board at Baltimore, has been transferred to New York as assistant head of the European and Mediterranean Trades Division. Donald F. Washburn succeeds Mr. Bradley as traffic manager at Baltimore.

FRANK E. BOYD, formerly of the marine department of the Westinghouse Electric and Manufacturing Company, has been appointed general sales manager of the Harrisburg Foundry and Machine Works, builders of the dual clearance "Unaflow" and piston valve engine.

F. P. GUTHRIE, head of the Radio Division Operating Department of the Emergency Fleet Corporation, has been designated by Chairman Lasker as the representative of the Shipping Board and Emergency Fleet Corporation to serve as a member of the inter-departmental committee on electrical communications.

N. A. SMYTH has been elected president of the United States P. and I. Agency, Inc., a new organization with headquarters at 25 Broadway, New York, which has recently been set up by the United States Shipping Board to take over the protection for its ships now handled by the Steamship Owners' Association.

A. F. MACK, North Atlantic district manager of the Emergency Fleet Corporation of the United States Shipping

Board, has tendered his resignation on account of pressing business interests. He will be succeeded in this office by W. J. Love, vice-president and general manager of the Emergency Fleet Corporation.

S. W. PIERCE, who since the war has been actively associated with the United States Shipping Board and for more than two years was the head of its South American and West Indies freight department, has resigned to become vice president of W. E. Hodges and Company, 25 Beaver street, New York, steamship agents and freight brokers.

DEAN J. HANSCOM, formerly foreign passenger agent of the Admiral Oriental Line, Seattle, Wash., has been appointed general agent of the company. Mr. Hanscom was one of the pioneers for the company when it opened its offices in the Orient in 1918, where he spent three years. He later returned to Seattle where he became foreign passenger agent.

L. L. BATES, foreign freight agent of the Admiral Oriental Line, Seattle, Wash., has been appointed general freight agent of the Line. Mr. Bates began his service with the company as a dock hand. Following his appointment as foreign freight agent he made a trip to the Orient to study conditions which was soon followed by his present promotion as general freight agent.

H. B. TAYLOR, who has been well known about New York as chief turbine engineer for the United States Shipping Board, has resigned to accept an appointment as marine superintendent with the Pacific Mail Steamship Company of San Francisco, California. He will have charge of the 535-foot passenger ships which this company is operating. Mr. Taylor's first engineering experience was obtained as an employee of the Parsons Steam Turbine Company in Great Britain. He subsequently became associated with the marine industry on the west coast of America, some thirteen or fourteen years ago, and held various executive positions in the shipbuilding and repair plants in Seattle and British Columbia. About three and a half years ago he accepted an appointment with the Shipping Board. He first joined the board in Philadelphia and was assigned to duty as an engineering inspector. After about one year he was transferred to the repair department at New York as chief turbine engineer and later assumed the duties of chief inspector as well, which positions he held up to the time of his resignation on December 15, 1922.

GEORGE W. WALKER has been appointed chief turbine engineer for the New York office of the United States Shipping Board, to succeed H. B. Taylor, resigned. Mr. Walker's appointment was received with great satisfaction by his associates, who have found him a well-balanced executive as well as an able engineer. He received his early training abroad and took to the sea while a young man. After following the sea for a number of years and obtaining his license as a marine engineer, Mr. Walker became interested in power plant work and was subsequently engaged in this branch of engineering in Chicago for a period of ten years. He maintained a lively interest in marine engineering, however, and still holds his license as marine engineer.

Mr. Walker first became identified with the Shipping Board about four and a half years ago, when he was appointed resident inspector at the plant of the Westinghouse Electric Company at East Pittsburgh, Pa. After serving as resident inspector at the Westinghouse plant for about two years, he was transferred to the New York office to assume the duties of assistant chief turbine engineer. These duties he has carried out for two years and a half, with credit to himself and the Shipping Board, his efficiency in handling the tasks assigned him resulting in the promotion just received.

Shipbuilding, Reconditioning and Operation

Port Expansion, Passenger and Freight Activities and Other
Notes of Interest in All Branches of the Marine Industry

Over \$318,000,000 Worth of Marine Work In 1921-22—Now for the New Year

IT is apparent that 1922 closed with business in much better condition than even the most optimistic had dared hope. Statistics compiled by MARINE ENGINEERING AND SHIPPING AGE show that there was reported in its columns in 1922 a total of more than \$84,981,517 worth of vessel construction and reconditioning work, when it was in contemplation, and over \$50,242,824 in contracts placed for similar work. In addition to this, there was also carried information on approximately \$88,106,661 worth of port work in contemplation with contracts awarded for such enterprises amounting to over \$11,286,004. For the year 1921, information was reported on all classes of marine work having a value of more than \$83,000,000, the total for the two-year period covering vessel construction, reconditioning, port and pier development, equipment, etc., well in excess of \$318,605,006.

To say that 1923 will start auspiciously is no exaggeration as inquiries by MARINE ENGINEERING AND SHIPPING AGE as to the prospects for the new year show encouraging results. It is expected that the first six months of 1923 will be featured by the placing of contracts for at least four new combination passenger and freight ships, reported during 1922 as in contemplation, and having a total estimated valuation of \$6,000,000. In addition to this new construction work, which at the present time seems practically assured if present plans are carried out, \$6,500,000 worth of ship reconditioning work involving the steamships *Agamemnon*, *Mount Vernon*, *President Grant* and *America* will also be in the hands of American shipyards during the early part of 1923.

Next Marine Show

Nov. 5-10, Architects

Meet Nov. 8 and 9

THE third annual exposition of the American Marine Association will be held in the Grand Central Palace, New York City, during the week of November 5-10, 1923, according to latest official announcement. In conjunction with the exposition, the Society of Naval Architects and Marine Engineers will hold its 31st annual convention November 8-9, the society's annual banquet being held on the evening of November 9 at the Waldorf-Astoria Hotel.

Reconditioning Bids

Rejected; New Boats

Planned Instead

IT is learned through the firm of Chapman & Fisher Company, Inc., consulting engineers and naval architects, Philadelphia, Pa., that the bids recently taken for the rebuilding of the passenger steamer *New Jersey* for the account of the Burlington Island Amusement Company have been set aside. The lowest figure submitted was \$119,500.

It is understood that instead of rebuilding the *New Jersey* the owners have decided to build new vessels. Plans for these proposed boats are expected to be complete during the first part of the year.

The Chapman & Fisher Company have also taken over a proposition to engineer and construct a water terminal along the Atlantic Seaboard.

Plans and Specifications in Course of Preparation for Overhauling Four Ships

The *Agamemnon*, *Mount Vernon*, *President Grant* and *America*
to be Put Into Service—America Out First With Specifi-
cations to Bidders in From Four to Six Weeks

SIX and one-half million dollars worth of ship reconditioning work on the biggest American merchant ships will be placed during the early part of 1923, according to data obtained by MARINE ENGINEERING AND SHIPPING AGE. Marked official activity has been evidenced with regard to the steamships *Agamemnon*, *Mount Vernon*, *President Grant* and *America*. Naval architects and draftsmen are already at work on the preparation of plans and specifications for the *America* contract and the *President Grant*, *Agamemnon* and *Mount Vernon* will follow in their turn.

AGAMEMNON-MT. VERNON

It is learned that on November 10, Shipping Board Commissioner Lissner, Vice-Presidents Love and Sheedy, Captain Bookwalter (in charge of the laid-up fleet), George Nichols (Assistant to Vice-President Sheedy), William F. Gibbs (naval architect in charge of reconditioning the *Leviathan*); C. A. Peterson and W. L. Bunker, representing the United States Lines, made an inspection of the *Agamemnon* at Hoboken, N. J. The *Mount Vernon* is at Boston and it is understood that Shipping Board officials have reported favorably to Chairman Lasker on the subject of reconditioning these two ships. It is estimated that the cost of the work proposed to be

done on the *Agamemnon* and *Mount Vernon* will reach a total of close to \$5,000,000 or two and one-half million, each.

Following the inspection of the *Agamemnon* by the officials mentioned above it was announced that the Board would appoint a Survey Board to make a complete inspection, or what is known as a scientific survey, of the two ships. So far as known at this time the personnel of this board has not been decided.

THE "BIG FOUR"

It is learned that according to present plans the *Leviathan*, undergoing reconditioning by the Newport News shipyard, at a contract price of \$8,200,000, will be taken
(Continued on page 56)

\$6,500,000 Repairs

(Continued from page 55)

over by the United States Lines. This great ship, it is stated, is to be run jointly with the *George Washington*, the *President Harding* and the *President Roosevelt*. These vessels, forming the main portion of the United States Lines fleet and operating in conjunction with each other, will form an enviable "Big Four," ranking as leaders of the world's transatlantic passenger carriers.

RECONDITIONING AUTHORIZED

According to reliable advices obtained by MARINE ENGINEERING AND SHIPPING AGE, the Shipping Board has authorized the reconditioning of the steamships *America* and *President Grant* as cabin and third class passenger ships. The *America*, the second largest ship in operation under the American flag, is now in the service of the United States Lines as a first, second and third class carrier. After a few more trips she will be withdrawn from the route for cabin conversion. This work will include the alterations and installations necessary for the accommodation of about 800 cabin and 1,200 third class passengers in rooms. The ship will re-enter the United States Lines' service for the early summer season.

The *America* has an overall length of 687 feet, beam 74 feet 3 inches, depth 52 feet 5 inches and speed about 17 knots. It is expected that after her conversion she will be the largest cabin carrier in the world.

Latest reports indicate that the *America's* reconditioning will be carried out under the direction of Captain R. D. Gatewood, Manager of the Maintenance and Repair Department of the Shipping Board. Preparation of plans and specifications will be done under the supervision of C. A. Petersen, naval architect for the United States Lines, and A. D. Woods, naval architect for the Shipping Board, Maintenance and Repair Department.

The specifications will cover the reconditioning of the hull and machinery; the rearrangement of present and installation of additional public rooms; overhauling the present and, wherever necessary, the installation of new systems such as ventilating, heating, electric, sanitary, etc. Specifications will probably be available to bidders in from four to six weeks.

THE PRESIDENT GRANT

In the case of the *President Grant*, the ship is to be reconditioned as a cabin and third class carrier, also for the United States Lines, to be run in conjunction with the *America*. Although no details were available at present as to who will prepare the plans and specifications for this contract, it is learned that the work has been authorized. It will include, among other things, the installation of new decks, the alteration of present and installation of new cabin accommodations, lifeboats, davits, re-equipment and refurnishing of new passenger accommodations, overhauling of engine and boiler rooms, main and auxiliary machinery, the ship's electric, ventilation, pump, sanitary systems, etc.

Wilmington Iron Works Low Bidder For Steel Barge

THE Wilmington Iron Works has low bidder for the construction of one 60-foot by 22-foot by 4-foot steel barge, at the opening of tenders at United States Engineer Office, Wilmington, N. C., December 26.

Plans and Specifications Out For Construction of Two Eastern Ships To Cost About \$3,500,000

First Big Job of New Year Provides For Highly Modern Passenger Steamers For New York-Boston Night Run—Will Be 402 Feet Overall Length, Turbine Driven, Oil Burning, For Express Service.

PLANS and specifications have been issued for the construction of two passenger steamers for the Eastern Steamship Lines, Inc., of which Calvin Austin, India Wharf, Boston, Mass., is president, bids to be received until about January 10, at the office of the designer of the vessels, Theodore E. Ferris, naval architect and marine engineer, of 30 Church street, New York City. It is believed the two ships will cost a total of close to \$3,500,000. A period of fourteen months is allowed for the delivery of the first vessel and fifteen months for the second.

Each steamer will have a length overall of 402 feet, length on 15-foot waterline 396 feet 4 inches, length between perpendiculars 385 feet, beam over guards 72 feet 6 inches, beam at 16-foot 6-inch waterline 56 feet 6 inches, depth molded to main deck at side 23 feet 9 inches, load draft 16 feet 6 inches. The steamers will be turbine driven and oil burning and will be put into service as night boats between New York and Boston, operating through the Cape Cod Canal, having a nominal speed of 17 knots with a possible maximum speed of 19 knots. The displacement on a 16-foot 6-inch draft will be 5,300 tons.

It is intended that the steamers will carry but one grade of passengers in rooms and in separate open spaces for berth travel of men and women. The total number of regular passenger rooms (two persons each) will be 267; de luxe rooms with adjoining baths (two persons each) 14; special rooms with adjoining toilets (two persons each) 64; or a total of 345 rooms accommodating a total of 690 passengers; while the berth travel is to accommodate 160 men and 50 women, making accommodations sufficient for the care of a total of 900 passengers.

The vessels will be twin screw, steel, sponson-sided type with freight space on the main deck and one freight hold, constructed with transverse framing, having complete double bottom and will be modernly equipped in every respect. The steamers will be equipped with lifeboats under davits with collapsible boats stowed under. This equipment is to consist of four metallic lifeboats, 24 feet by 7 feet by 3 feet, for 30 persons each; twelve

metallic lifeboats, 26 feet by 7 feet 9 inches by 3 feet 4½ inches, for 40 persons each; and twelve collapsible lifeboats, 24 feet by 7 feet by 2 feet, for 40 persons each. It is understood that the steamships are not to be built under the inspection of any classification society but all materials must fulfill mill tests required by the rules of the American Bureau of Shipping.

PROPELLING MACHINERY

The propelling machinery will consist of two latest design Parsons' single reduction gear steam turbines and six cylindrical return tube Scotch boilers, 16 feet 4 inches inside diameter by 11 feet 8 inches long over top heads, built for a working pressure of 200 pounds per square inch, and one donkey boiler, vertical, wet uptake type, 6 feet inside diameter by about 101 inches high for use during the winter layup period of the steamers, built for 150 pounds per square inch working pressure.

The twin screw turbine propelling machinery will be built from designs furnished by the Parsons' Steam Turbine Company, Ltd., of Wallsend-on-Tyne, England, and each set will consist of one high pressure and one low pressure ahead turbines in series, each driving a separate pinion through single reduction gearing. Astern turbines of the impulse type will be incorporated in each low pressure ahead turbine. The revolutions of the turbines at full power ahead will be as follows: high pressure turbines, 1,920 revolutions per minute and the low pressure turbine, 1,920 revolutions per minute and at these revolutions, developing a total of not less than 6,400 shaft horsepower. The speed of the propellers under these conditions will be 120 revolutions per minute.

BOILERS

The six boilers will be arranged for two firerooms, with grates fore and aft, and will be fitted with the Howden system of heated forced draft. The total effective heating surface of the boilers will be about 21,000 square feet. The furnace fronts of each boiler are to be arranged for burning oil fuel on the White system, as manufactured by the Todd Shipyards Corporation.

Construction of New Mississippi Steamer Proposed

CAPTAIN GORDON GREENE, of Cincinnati, O., is contemplating the building of a new stern wheel, all steel, river steamer, according to information obtained by MARINE ENGINEERING AND SHIPPING AGE. The boat will be of the Mississippi River type, about 170 feet long, and is to take the place of the steamer *Tacoma*, recently destroyed in a disastrous riverfront fire at Cincinnati. Captain Greene proposes to use as much of the machinery of the burned steamer as is possible in the new boat and will probably build new boilers.

Bids Open Jan. 27 at Florence, Ala., For Four Barges

UNITED States Engineer Office, of Florence, Ala., will receive sealed proposals until 11 A. M., January 27, for the construction and delivery of four steel barges to be delivered at Paducah, Kentucky.

The boats will have a length molded of 120 feet, beam molded 36 feet, depth molded 7 feet 6 inches. Each barge will be equipped with deck fittings including four 36-inch cleats, four 7-inch double bitts and four 30-inch open chocks, all of cast steel and of approved design.

Secretary Hoover Assures Standardization Committee Hearty Support at First Meeting

THE first meeting of the general committee appointed by Col. E. A. Simmons, chairman of the informal conference on elimination of waste in ship construction and operation through standardization held at the Grand Central Palace, New York City, on November 10 last under the auspices of the American Marine Association, convened at the Department of Commerce, Washington, on December 20. There were present Charles F. Bailey, Engineering Director of the Newport News Shipbuilding & Dry Dock Company, representing the shipbuilders for machinery; Hugo P. Frear, Naval Architect of the Bethlehem Shipbuilding Corporation, representing shipbuilders for hull construction and hull fittings; Commander R. D. Gatewood, representing the U. S. Shipping Board; W. F. Gibbs, representing the American Steamship Owners' Association; Capt. C. A. McAllister, representing the American Bureau of Shipping; Capt. John F. Milliken, representing masters, mates and labor organizations; E. H. Rigg, Naval Architect of the New York Shipbuilding Corporation, representing the Society of Naval Architects and Marine Engineers; Rear Admiral Robert Stocker, U. S. N., representing Admiral J. K. Robison of the Bureau of Engineering of the Navy Department, who was unable to be present; Brig. Gen. H. Taylor, representing (unofficially) the Corps of Engineers, U. S. Army; Capt. J. T. Tompkins, U. S. N., who represented the Bureau of Construction and Repair of the Navy Department in place of Rear Admiral J. D. Beuret; and Gen. George Uhler, representing the Steamboat Inspection Service of the Department of Commerce. Rear Admiral W. S. Benson, of the U. S. Shipping Board, also attended the meeting at Col. Simmons' invitation; while the Department of Commerce was represented by Ray M. Hudson of the Division of Simplified Practice. The meeting was called to order at 10:30 A. M. by Chairman Simmons, who then presented the Hon. Herbert Hoover, Secretary of Commerce.

Mr. Hoover, who made his personal interest in the movement known at its inception, expressed his views in general of the possibilities for standardization in the marine field and told of the work of the Department of Commerce in other industries. He also assured the committee that it could depend upon the hearty support of the Department which, however, would at no time attempt to dictate.

Mr. Hoover was followed by W. A. Durgin, Chief of the Division of Simplified Practice of the Department of Commerce, who illustrated his views of possibilities for standardization in shipbuilding by supplementing Mr. Hoover's remarks to the extent of amplifying what he had said about results by a detailed description of actual accomplishments, especially in manufactured lumber and bricks. While Mr. Durgin acknowledged that those industries were hardly comparable with shipbuilding, he pointed out that the principle was basic and then showed its application to ships' parts by concrete examples.

Admiral Benson then told of the two conferences in his office, one on November 16 and another on December 13, with representatives of shipbuilders and manufacturers of electrically operated auxiliaries called for the purpose of determining what, if anything, could be done in the matter of standard designs and specifications for Diesel en-

gine installations for the some five types of steam propelled vessels that the Shipping Board is offering for sale. He explained that because of the acknowledged superiority in low operating and maintenance costs of Diesel engines for ships of approximately the tonnage of those under discussion (3,000 to 9,600 tons) and the number of vessels involved, quantity production and lower costs would be possible if the equipment could be standardized. The result of the two meetings was that the more important yards in the United States have been asked by Admiral Benson to reduce their respective ideas to tentative plans and specifications for use as the basis for a third conference to be held at some convenient point, perhaps Philadelphia.

Following Admiral Benson's talk, the committee proceeded to discuss the form the permanent organization should take, with the result that it was decided to follow the British panel plan by dividing the United States into three panels—(1) Atlantic Coast and Gulf; (2) Great Lakes; and (3) Pacific Coast. Within each panel there will be a series of small sub-committees, to which will be assigned the task of determining certain specified standards. That the time and expense involved shall be reduced to the minimum, most if not all of the sub-committees will be divided territorially as to membership, with groups in the various shipping centers, the work of all to be correlated by occasional joint meetings of one or more members from each committee or by the persons who must necessarily be employed to take care of the details of the operations of the organization as a whole. Each sub-committee will be composed of men well qualified to represent the shipbuilder, the shipowner, the ship operator and the Navy, to which will be added representatives from the Army and such other branches of the government as may be concerned—the Department of Commerce always included.

In addition to the three panels described, there will be one sub-committee which will deal with the subject of standardization of things which have to do exclusively with the loading and movement of ships other than the mechanical aspect.

The work of the several sub-committees will be directed by a central committee, the membership of which will be composed of the men designated by Col. Simmons to attend the Washington meeting, augmented from time to time as circumstances may dictate. It will approve all standards before issuance, including the settlement of any differences of opinion within the several sub-committees, define the policies of the organization as a whole and in general exercise executive direction of all major operations.

The chairman was authorized to appoint two special committees, one to acquaint the executive heads of all concerns in the field with the plans of the committee to the end that their hearty support will be assured; the other to survey the range of possibilities for standardization and list all items which, in its opinion, should be acted upon. Pending receipt of its report, it was decided to proceed at once with the appointment of sub-committees to act on those things which have already been thoroughly thrashed out by the British Engineering Standards Association, including such items as pipe threads, bollards, shafting, structural steel, steel for marine boilers and steel forgings and castings.

Million in New Contracts Placed on Great Lakes

THREE contracts for new vessel construction, involving the expenditure of a total estimated at close to a million dollars, have just been awarded to Great Lakes shipyards. They provide for the building of a steel cargo vessel, 334 feet long, by the Toledo Shipbuilding Company, of Toledo, Ohio, for the Huron Transportation Company, of Marine City, Mich., and the construction of two steel Diesel electric freighters, each to be approximately 258 feet long, by the Great Lakes Engineering Works, of Detroit, for the McDougall Terminal Warehouse Company, of Duluth, Minn.; these vessels to be built under the supervision of the American Bureau of Shipping.

Moore Yard Buys Lake Ships; May Convert to Oil

THE Moore Shipbuilding Company, Oakland, Cal., has purchased the cargo steamships *Lake Frances* and *Lake Cayuga*, each of 3,000 deadweight tons, from the Shipping Board. These ships are now at Newport News being fitted out for the voyage to the west coast. It is understood that these vessels will be converted to oil burners and that they will be engaged as lumber carriers.

Boiler Contract Placed For Two River Steamers

THE California Navigation Company, of San Francisco, has placed a contract with the Power Specialty Company for four Foster marine boilers to be used on two rivers steamers which the company is to build for the run between San Francisco and Sacramento. Each boiler will have about 3,050 square feet of heating surface and is to be equipped with Foster Superheaters. Other details of the proposed vessels are not yet completed.

Greenbay Yard is Lowest Bidder For Five Steel Barges

THE Greenbay Dry Dock Company, Greenbay, Wis., in submitting a figure of \$72,400, for the construction of five barges and the installations of derricks, submitted the lowest bid at the opening of proposals by United States Engineer Office, Milwaukee, Wis., on December 20. The proposed boats are to be built of steel, 100 feet in length, beam 30 feet and depth 6 feet. Two of the boats are to be equipped with derricks and derrick machinery. The tenders submitted were as follows:

Greenbay Dry Dock Co.....	\$72,400
Penn Bridge Co.....	81,810
Dravo Contracting Co.....	92,040
Manitowoc Shipbuilding Corp.....	95,500
Defoe Boat and Motor Works.....	113,000

Outboard profile and general arrangement plan of 24-inch pipe line dredge to be built for United States Engineer Office, Cincinnati, O. The vessel is to be built of steel, 175 feet molded length, 50 feet molded breadth and 8 feet depth. The main dredging pump will be driven by Diesel engines and she will be fitted with electrically driven equipment. Bids are to be opened January 20, 1923. A detailed description of the vessel and auxiliaries was published in these columns on December 16.

Bids to Be Opened January 5 by Engineer Office, Cincinnati, for Diesel-Electric Pipe Line Dredge

Proposed Vessel Will Have Molded Length of 175 Feet, Molded
Breadth 50 Feet, Built to American Bureau Rules—
Equipment Will be Extensive and Modern.

SEALD proposals for the construction of one 24-inch Diesel-electric pipe line dredge will be received by the United States District Engineer Office, Cincinnati, Ohio, until January 5, 1923. The vessel is to have a molded length of 175 feet, molded breadth 50 feet and molded depth 8 feet. The dredge and equipment, unless otherwise specified, is to be built to the American Bureau of Shipping Rules. The contracting officer will furnish F. O. B. railroad cars or at wharf at contractor's yard, one dredging pump engine, 1,000 brake horsepower, non-assembled (McIntosh & Seymour type M-6-C-44), type suitable for direct connection to main dredging pump, together with mufflers with heating coils and various other auxiliary material. Bidders are invited to submit alternate proposals on at least three different makes of Diesel engines which will meet the specifications and the boat is to be delivered afloat at Fernbank, O.

EQUIPMENT

The vessel's "A" frame will be about 31 feet 10 inches long and at the upper end

will be fitted five 30-inch sheaves for wire hoisting rope for dredging ladder. There are to be two spuds, each 56 feet 9 inches long, over all, with an outside diameter of 34 inches. They are to be built of 30.6-pound steel plate.

A double-track, 10-ton traveling crane is to be provided and installed between frames 51 and 62, over the dredging pump, with a double-track traveling crane over the pumping engine between frames 31 and 51 and fitted with a 2-ton triplex trolley block, army type.

AUXILIARY ENGINES

Two auxiliary engines and generators shall be furnished and installed as shown on the plans. The engines shall be of the full Diesel, high compression, vertical, multi-cylinder, four-stroke-cycle, single acting, non-reversing, heavy duty type, capable of delivering continuously 150 kilowatts at 250 volts. The engines are to develop at least 225 brake horsepower. Accessories, equipment and spare parts for the auxiliary engines are also to be supplied.

S.S. Lake Sebago To Be Converted For Oil Burning

THE cargo steamship *Lake Sebago* of 3,000 deadweight tons, which has just been purchased by the Oregon Spruce Corporation from the Shipping Board, is to be converted to an oil burner. Specifications covering the job have been sent to both the east and west coasts. It is understood that this company is now dickering with the Shipping Board and will probably purchase more of the same class of ships. The vessel is 252 feet in length, 43 feet 6 inches in beam and draws 18 feet of water. She is fitted with triple expansion engines and cylindrical return tubular boilers.

Liner Roosevelt Repairs Awarded Robins Shipyard

THE Robins Dry Dock & Repair Company was successful bidder for general repair work on the steamship *President Roosevelt*, for the United States Lines, similar in nature to repairs on the *President Harding*, which were as follows: General repairs, minor betterments and providing of steam heat for various sections of the ship, new generators, feed water heaters, distillers and deck alterations. Bids for the work were opened Friday, December 8. The work will cost \$63,000.

Two Standard Oil Contracts Awarded N. Y. H. Plant

THE contract for repairs to the steamship *Charles H. Pratt*, of the Standard Oil Company of New Jersey, has been awarded the New York Harbor Dry Dock Company, as a result of the bids opened on December 14. The tenders submitted were:

New York Harbor.....	\$23,663
Newport News.....	23,735
Morse.....	27,085
Todd.....	33,832

The New York Harbor plant was also awarded the work of making general repairs to the steamship *Baltic*, also of the Standard Oil Company of New Jersey fleet, bids for which were opened December 13. The prices were:

Newport News.....	\$11,754
New York Harbor.....	12,060
Morse.....	15,600
Robins.....	15,909

Three "President" Ships To Be Equipped With Aero Alarm System

The Aero Alarm Company has been awarded the contracts to make extensions of the Aero Alarm System throughout the steamships *President Roosevelt* and *President Harding*, now being reconditioned at Robins Dry Dock & Repair Company, Brooklyn, N. Y.

The company has also been awarded, through the Seattle office of the Todd Shipyards Corporation, the contract for making extensions of the Aero Alarm System on the *President Harrison* now lying at San Francisco.

Radio Installed on Morgan Liners

Radio sets have been installed on the passenger steamships *Momus*, *Comus* and *Creole*, the three ships in the Morgan Line service between New York and New Orleans, according to an announcement made by L. J. Spence, director of traffic of the Southern Pacific Lines.

"There is nothing more modern than radio," said Mr. Spence, "and these installations are an earnest of the desire and intention of the officers of the line to keep the service strictly up to date in every respect."

Greenbay Dry Dock Company Low Bidder for Construction of Ten 100-Foot Steel Barges

THE Greenbay Dry Dock Company, of Greenbay, Wis., with a total price of \$107,740 or \$10,774 for each boat, was the low bidder for the construction of ten steel barges, at the opening of tenders by

American Ships Must Pay Fifty Percent Tax On Repairs Made In Foreign Ports Under New Ruling

REGULATIONS governing the carrying out of repair work on American vessels in foreign ports and providing for the payment of a fifty per cent tax for such work, except where the vessel is compelled by stress of weather or other casualty to put into a foreign harbor for repairs or purchase of equipments, have been issued by the Treasury Department, United States Customs Service. The provisions of the act are as follows:

TREASURY DEPARTMENT
United States Customs Service
New York, N. Y., December 4, 1922

TO STEAMSHIP OWNERS, COMPANIES, AGENTS, AND
OTHERS CONCERNED.

Your attention is invited to Section 466, Act of September 21, 1922, amending Sections 3114 and 3115 of the Revised Statutes which provides that "the equipments, or any part thereof, including boats, purchased for, or the repair parts or materials to be used, or the expenses of repairs made in a foreign country upon a vessel documented under the laws of the United States to engage in the foreign or coasting trade, or a vessel intended to be employed in such trade, shall, on the first arrival of such vessel in any port of the United States, be liable to entry and the payment of an ad valorem duty of 50 per centum on the cost thereof, in such foreign country; and if the owner or master of such vessel shall wilfully and knowingly neglect or fail to report, make entry, and pay duties as herein required, such vessel, with her tackle, apparel and furniture, shall be seized and forfeited."

If the owner, or master of such vessel, however, furnishes good and sufficient evidence that such vessel, while in the regular course of her voyage, was compelled, by stress of weather or other casualty, to put into such foreign port and purchase such equipments, or make such repairs, to secure the safety of the vessel to enable her to reach her port of destination, then the Secretary of the Treasury is authorized to remit or refund such duties, and such vessel shall not be liable to forfeiture, and no license or enrollment and license, or renewal of either, shall hereafter be issued to any

such vessel until the collector to whom application is made for the same shall be satisfied, from the oath of the owner or master, that all such equipments and repairs made within the year immediately preceding such application have been duly accounted for under the provisions of this and the preceding sections, and the duties accruing thereon duly paid; and if such owner or master shall refuse to take such oath, or take it falsely, the vessel shall be seized and forfeited."

Equipments. The term "equipment" includes portable articles necessary or appropriate for the navigation, operation, or maintenance of a vessel, such as rigging, sails, anchors, chains, cables, tackle, boats, repair parts, life-saving apparatus, nautical instruments, signal lights, lamps, furniture, carpets, table linen, table ware, bedding, arms, munitions, and articles of a similar nature, but not such articles as are permanently incorporated in or permanently attached to its hull or propelling machinery and does not constitute consumable supplies.

Sea Stores. Sea stores embrace all articles for the use and consumption of the passengers and crew of a ship upon its voyage and all commodities which are consumed in their use.

(1) The Department advises that articles such as soda, kerosene, varnish, turpentine, etc., which are consumed in their use, are not subject to duty.

(2) Articles which are purchased for repair purposes on a vessel, such as paint, for example, though coming under the head of sea stores, are subject to duty.

Ship's Stores and Equipment. Ship's stores and equipment are held by the Department to be identical terms.

Repairs and Materials. Repairs made at the port of destination, when such repairs are due to stress of weather during the voyage, are not exempt from duty. Materials drawn from the vessel's equipment or sea stores and used for repairs are dutiable.

Labor. If the labor is performed by other than the ship's complement, charges for labor should be included in the value of such repairs. If the labor is performed by members of the ship's complement and an additional compensation is paid them for such repair work, such additional compensation constitutes a part of the cost of the repairs and is dutiable.

Cleaning. Cleaning and scrubbing of parts of the ship's equipment, such as stoves, window curtains, etc., does not constitute repairs and is not subject to duty.

Entry. Consumption form of the entry will be used and it is very essential to the expeditious handling of repairs under Section 466 that a statement of the cost of repairs made abroad be filed at the time of entry. The consumption entry should be filed and the duties, if any, paid or secured to be paid, immediately after entry of the vessel.

Protest. If dissatisfied with the decision of the collector as to the rate and amount of duties assessed, the importer or owner, or his agent, may file a written protest as provided for in Section 514 of the Tariff Act of 1922, and have the question or questions determined by the Board of United States General Appraisers.

Prompt and cheerful compliance with these regulations is respectfully solicited.
(Signed) H. C. STUART, Acting Collector.

Greenbay Dry Dock Co.....	Greenbay, Wis.	\$10,774.00

Among the Steamship Operators

Beginning this month, the Garland Steamship Corporation will add seven modern steamers, totaling more than 59,000 tons, to their coast to coast service via the Panama Canal. There will be sailings every two weeks both east and west bound, the ports of call being New York, Baltimore and Norfolk on the Atlantic and Los Angeles, San Francisco, Seattle and Portland on the Pacific, the vessels maintaining the sailings as to ports in the order named.

Several reductions and changes in prevailing freight rates have been authorized by the Continental Freight Conference. Among them were the general cargo rate to Antwerp and Rotterdam, which was reduced from 75 cents and 40 cents a hundred pounds to 70 cents and 35 cents. To Hamburg and Bremen the general cargo rate was lowered from 82½ cents and 45 cents to 75 cents and 37½ cents.

November marked the inauguration of a semi-monthly service from San Francisco and Los Angeles to the West Coast of Mexico with the sailing of the German steel motorship *Principio*, a twin screw vessel of 1,000 tons deadweight, owned by the United Fruit Distributors, Inc., of Los Angeles. Refrigerator equipment has been placed on the vessel for the handling of bananas, which will be the main cargo northbound. The vessel was purchased recently in Hamburg and the possibilities are that her registry may be changed.

Gulf shipyards have reduced drydocking rates from 20 cents a ton for the first day and 15 cents thereafter to 16 and 14 cents.

Vessels of the Commercial Pacific Line in the coast to coast trade now call at Norfolk for cargo. Hasler & Co. are handling the ships there. The Commercial Line is an old established concern, now operating out of Baltimore, New York, Philadelphia, Los Angeles, San Francisco, Portland, Ore., Vancouver and Seattle. Including the Isthmian Line, which has had two ships at Norfolk recently, the number of coast-to-coast lines giving service at Hampton Roads will be six.

Sailings from Boston in the London, Hull and Leith service of the Oriole Steamship Lines will in the future, include a call at Dundee, Scotland, to discharge and load freight. The North Atlantic & Western Steamship Company of Boston is agent for the operating company.

Sailings from Boston to the Far East have been arranged by the Toyo Kisen Kaisha, Japanese Steamship Company, and the service will be permanent, if conditions warrant.

The Baltimore Steamship Company has decided to add a passenger feature to its line to Porto Rico. This step has been taken because of the growing business relations between Baltimore and the West Indies. The *Governor John Lind*, upon its arrival at Baltimore from San Juan, went to the plant of the Baltimore Dry Docks to be fitted with 16 staterooms for passengers. It is expected that the running mate of the *Lind*, the *Major Wheeler*, will also be re-conditioned in a similar manner.

W. J. Love, vice-president and general manager of the United States Shipping Board Emergency Fleet Corporation, in charge of traffic, has announced the inauguration of a new line of Shipping Board passenger steamers to be operated from Pacific Coast ports to the east coast of

South America, via the Panama Canal. The new service will be managed by Swayne & Hoyt, of San Francisco, as agents for the Board, and, in addition to the three cargo vessels now allocated to them by the Fleet Corporation, they will operate the fast passenger steamers *President Hayes*, *President Harrison* and the *Susquehanna*. In addition to passenger accommodations, the last named steamships are equipped for miscellaneous and refrigerator cargoes. The ports of call will be Seattle, Wash.; Portland, Ore.; San Francisco, Cal.; Panama Canal; Porto Rico; Rio de Janeiro; Montevideo and Buenos Aires, on southbound trips, and in addition to these ports, the vessels will stop at other east coast South American ports on the northbound trip for coffee. This line will open a new territory for Pacific Coast merchants and products. It will tend to develop the fruit trade of the northwest with the east coast of South America, particularly Brazil, where a marked demand is noted for American apples. It is proposed to install a service whereby sailings will be made every three weeks in each direction. Business men and tourists who desire to visit the west coast of South America can take this new line to the Panama Canal and then transfer to an American vessel running to ports on the west coast to South America. It will also give direct communication with Porto Rico and from Porto Rico to all east coast ports.

Effective in November, Mrs. E. R. Clotworthy was appointed director of steamer and passenger service, in charge of service on steamers and local passenger business, between Baltimore and Norfolk, including solicitation and advertising in connection therewith, reporting to W. L. Seddon, of the Baltimore Steam Packet Company.

Following meetings of the North Atlantic Conference in New York and Brussels, the steamship lines agreed to make certain reductions in the first class fares on all Atlantic lines except those going to the Mediterranean. There will be very small reductions on liners such as the *Majestic* and *Aquitania*, due to heavy operating expenses, and it will be very little more than 5 per cent on the Liverpool ships like the *Baltic* and *Carnania*. The chief reduction will be in the minimum first cabin rates of the older ships like the Red Star liners *Kroonland* and *Finland* and the Holland-American liners, *Noordam* and *Ryndam*. This will be more than 12 percent, considering speed. There will be no reduction in the second and third class fares on the Atlantic lines.

The Far East Steamship Company, 78 Broad Street, New York, started a service late in December from New York to Hong Kong, Kobe and other Far East ports. One steamer, the *Culgoa*, has been acquired under the American flag and negotiations are under way with Chinese interests for another vessel.

The Shipping Board has announced the sale of two tankers and one steel cargo vessel. The tankers are the *Utacarbon* and the *Cathwood*, both 10,078 deadweight and 7,076 gross tons, sold to the Union Oil Company of Los Angeles, while the steel cargo vessel is the *Delvosa*, 5,125 deadweight tons and 3,474 gross tons, sold to the Alaska Steamship Company of Seattle, Wash.

The East Coast South American Conference met recently and reduced the rate on

paint to Montevideo and Rio de Janeiro from \$20 to \$16 a ton.

A successful trial test was made of the steel steamship *State of Maryland*, under construction at the Pusey & Jones Company for the Old Bay Line. A speed of 18.6 knots was attained. The vessel is a sister ship of the *State of Virginia*, launched some months ago by the Pusey & Jones Company. Both vessels will be used on Chesapeake Bay.

The Three Star Line has arranged for a resumption of its full service to North African ports, Marseilles and Genoa.

The steamer *Fred G. Hartwell*, building for the Franklin Steamship Company, H. K. Oakes, manager, was successfully launched at Lorain, O. The *Hartwell*, which will be completed this month, will be 617 feet overall, 596 feet keel, 64 feet beam and 33 feet deep. She will have a triple expansion engine and steam will be furnished by three Scotch boilers, 14 feet in diameter and 11 feet long.

For the purpose of establishing the fastest and best service between Seattle and the Orient, the five large trans-Pacific liners, operated by the Admiral Oriental Line, were placed on a 12-day schedule beginning December 9. The ships formerly sailed every two weeks, remaining in Seattle, the home port, for 18 days.

Business Notes

The Ingersoll-Rand Company and the A. S. Cameron Steam Pump Works announce the opening of a branch office at 718 Ellicott Square Building, Buffalo, N. Y. This new office is equipped to render full service to those interested in air, gas and ammonia compressors, vacuum pumps, turbo blowers and compressors, condensers, oil and gas engines, pneumatic tools, rock drills, centrifugal and direct-acting pumps and other products manufactured by these companies.

It is announced from Cleveland, Ohio, that the following companies are now doing business under the name of The Columbia Steamship Company, as a result of consolidation: The Hubbard Steamship Company, Montreal Transit Company, Castile Transit Company, Miller Transit Company, Hanna Transit Company, Norton Transit Company, Ft. Henry Transit Company, Ottawa Transit Company, Bristol Transit Company and Yosemite Transit Company.

The Wilson Welder & Metals Company is now represented exclusively in Maryland, Virginia and the District of Columbia, by the Alexander Milburn Company of Baltimore. A large stock of color-tipped welding metals and plastic-arc welding machines is available at this point for distribution throughout the territory and a complete demonstration plant is in operation.

Mr. A. E. Jones, sales engineer in the New York office of the Terry Steam Turbine Company, has accepted a position with W. B. Connor, Inc., 90 West Street, New York City, in a similar capacity. Mr. Jones began his new duties January 1, 1923.

Mr. A. A. Heller has taken over the management of the International Oxygen Company in place of Mr. L. W. Hench, secretary and general manager, resigned.

Marine Construction News of the Month

Ship Contracts—New Ship Concerns and Shipyard Improvements—Terminal Projects—Government Contracts

SHIPS AND SHIPBUILDING

Steamer Overhauled, Portland, Ore.—Steamer Wawalon was placed on drydock at Portland for overhauling.

Tug Drydocked, Mobile, Ala.—The Alabama Dry Dock Company replaced broken propeller wheel on tug Hukey.

Repairs to Boiler, Oakland, Cal.—Santa Fe ferryboat San Pablo went to the Moore yards for repairs to her boilers.

Motorship Drydocked, Portland, Ore.—Motorship La Merced was lifted at the port drydock plant to be overhauled.

Tug Repaired, Mobile, Ala.—Tug James Dougherty went to Todd repair plant, Mobile, for repairs and general overhauling.

Drydocking Contract, Seattle, Wash.—The Todd Drydocks have received the contract for drydocking the Remus for repairs.

Steamers Drydocked, Portland, Ore.—Steamers West O' Rowa and Wawalong went on drydock at Portland for overhauling.

Schooner Repairs, Philadelphia, Pa.—The American schooner Mabel Gale went to Cramps' Shipyard for miscellaneous repairs.

Repairs to Plates, Superior, Wis.—Steamer Cayuga went to Superior to be drydocked for repairs to eighteen damaged plates.

Government Dredge Repaired, Portland, Ore.—Government dredge Col. P. S. Michie went to Portland to be drydocked for repairs.

Steamer Repaired, Brooklyn, N. Y.—Steamer Susquehanna was awarded the Atlantic Basin Iron Works for repairs at \$15,290.

Repairs and Overhauling, Seattle, Wash.—Admiral liner H. F. Alexander was placed on drydock for minor repairs and overhauling.

Tanker Drydocked, Chester, Pa.—The tanker J. M. Pew, of the Sun Oil Company's fleet, went into drydock at the Sun Shipyards.

Schooner Repairs, Orange, Tex.—The schooner Thelma has been shifted to the Southern Dry Dock yard to be hauled out for repairs.

Coast Guard Cutter Repaired, Fore River, Mass.—Coast Guard cutter Tampa went to the Fore River plant to undergo necessary repairs.

Miscellaneous Repairs, Chester, Pa.—The Shipping Board steamship West Inskip went to the Sun Shipyards for miscellaneous repairs.

Dredge Drydocked, Portland, Ore.—Dredge Portland, wrecked in collision, was towed to drydock to be salvaged of machinery and equipment.

Steamer Drydocked, San Francisco, Cal.—General Petroleum Company's steamer Hambro has been placed in drydock to be reconditioned.

Contract Awarded, Brooklyn, N. Y.—Alderton Dry Dock Company was awarded the contract for repairs to the steamship West Lashaway; price \$4,800.

Repair and Painting, Philadelphia, Pa.—Southern Steamship Company's vessel Algiers went to Cramp's yard to be drydocked for repairs and painting.

Overhauling of Lightship Relief, Winslow.—Lightship Relief No. 92 has been sent to Winslow to undergo overhauling, repairing and annual inspection.

Towboat Inspection, Pittsburgh, Pa.—Towboat Twilight, of the Rogers Sand Company fleet, underwent boiler repairs and was inspected shortly after.

Contract Awarded, Winslow.—The contract for repairing the motorship Anvil has been let to the Winslow Marine Railway and Shipbuilding Company.

Steamship Reconditioning, Brooklyn, N. Y.—The Morse Dry Dock & Repair Company was successful bidder, at \$168,270, for reconditioning steamship Reliance.

Steamer Drydocked, Seattle, Wash.—The steamship Memnon of the General Steamship Corporation's South American service has been drydocked at Seattle.

General Repairs, Baltimore, Md.—The Maryland Dry Dock Company received the contract for general repairs and painting on the Norwegian steamship Tajana.

Barges Repaired, Mobile, Ala.—Mississippi-Warrior Service barges No. 103, 205 and 210 were awarded to the Alabama Dry Dock Company for repairs.

Miscellaneous Repairs, Philadelphia, Pa.—The United States Army tug Vidette has gone to Cramps yard for miscellaneous repairs as a result of a collision.

Steamer Drydocked, Mobile, Ala.—Todd plant, Mobile, was awarded the contract to drydock and make general repairs to the Waterman steamer Clavarack.

Alteration Job, Oakland, Cal.—Contract for extensive alterations on the Associated Oil tanker Kewanee was awarded to Moore Shipbuilding Company, at \$18,900.

Calking of Deck, San Francisco, Cal.—Crowley Shipyard was awarded the contract, as low bidder, for work of calking main deck of the steamer Admiral Dewey.

Repairs to Steamer, Toledo, Ohio.—Steamer Arcurus, damaged in collision in the Detroit River, has gone to the yard of the Toledo Shipbuilding Company for repairs.

Contract Awarded, Staten Island, N. Y.—The New York Harbor Dry Dock Company has been awarded repairs to the Shipping Board steamship Waukegan on a bid of \$7,570.

Contract Awarded, Oakland, Cal.—The Moore Shipbuilding Company was awarded the contract for drydocking and other work on the Pacific Mail steamer Point Judith.

Steamer Drydocked, Oakland, Cal.—China Mail steamer Nanking went to the Moore yard to be drydocked to have new tailshaft installed and to be generally overhauled.

Repairs to Keel, Eagle Harbor, Wash.—Steamship Anyox, of the fleet of the Coastwise Steamship and Barge Company, has been shifted to Eagle Harbor for repairs to her keel.

Schooner Drydocked, Savannah, Ga.—Sally Wrenn has been placed on drydock at the Wilkinson Marine Railway and Dry Dock Company's plant to undergo survey and minor repairs.

Overhauling of Ship, Seattle, Wash.—The trans-Pacific liner President Jackson went to Todd Dry Docks for a thorough overhauling and to have her keel scraped and painted.

New Tail Shaft, Brooklyn, N. Y.—Work of supplying and machining new tail shaft for the steamship Munamar was awarded to the Robins Plant of the Todd Shipyards Corporation.

Repairs to Steamship, Staten Island, N. Y.—Contract for repairs to steamship Swiftscout has been awarded to the Staten Island Shipbuilding Company on tender of \$9,350 and 9 days.

Proposed Boat, Cincinnati, O.—Captain Gordon Greene, of Cincinnati, contemplates building new stern wheel, all steel, river steamer, 170 feet long and of the Mississippi River type.

\$6,500,000 Repair Work, New York.—\$6,500,000 worth of ship reconditioning work will be done early this year on the steamships Agamemnon, Mount Vernon, President Grant and America.

Two Shipping Board Contracts Awarded, Brooklyn, N. Y.—Shipping Board awarded steamship Zarembo to the Alderton Yards at \$2,000, and the Half Moon to the Crystal Iron Works, at \$1,043.

Liner Overhauled, San Francisco, Cal.—Pacific Mail liner President Lincoln went to the Bethlehem plant for general overhauling. All machinery and boilers were taken down and inspected.

General Overhauling, Newport News, Va.—The Merchants and Miners' Transportation Company's passenger ship Merrimack has gone to Newport News to be drydocked for general overhauling.

Contract Awarded, San Francisco, Cal.—The Eureka Boiler Works was awarded the contract for retubing work on the Matson motorship Annie Johnson and other minor adjustments on the vessel.

Contract Awarded, Brooklyn, N. Y.—Robins Dry Dock & Repair Company was awarded the contract for repair work on the steamship President Roosevelt, for the United States Lines. Price \$63,000.

Contract Awarded, Brooklyn, N. Y.—The Foreign Transport & Mercantile Corporation of New York awarded the contract for repairs to steamship Manitowoc to Alderton Dry Docks Company at price of \$3,797.

Contract Awarded.—The Bethlehem Shipbuilding Corporation has been awarded the contract by the United States Shipping Board to repair the steamship West Loquassak, cost to be in excess of \$10,000.

Contract Awarded, Brooklyn, N. Y.—Robins Dry Dock & Repair Company received the contract for reconditioning the steamship President Harding, the work providing for general repairs, minor betterments, etc.

Transport Reconditioning, San Francisco, Cal.—Transport Logan went to Bethlehem Yards, San Francisco, for extensive alterations on vessel's passenger accommodations and life-saving equipment. Price \$16,989.

Contract Awarded, Brooklyn, N. Y.—The Martha Washington, purchased by the Cosulich Line from the Shipping Board, has been taken to the yard of the Robins Drydock and Repair Company for a thorough reconditioning.

Reconditioning Work, Staten Island, N. Y.—The Staten Island Shipbuilding Company was awarded the contract for reconditioning work on the steamship Munamar, of the Munson Line, including about 400 feet of seam calking.

Aero Alarm System Installation.—The Aero Alarm Company has been awarded contracts to make extensions of the Aero Alarm System throughout the steamships President Harding, President Roosevelt and the President Harrison.

Boiler Installed on Government Tug, Portland, Ore.—Government tug Wilson, controlled by Washington district, corps of engineers, U. S. A., went to Portland to have new boiler installed, at plant of Willamette Iron & Steel Works.

Repairs, Oakland, Cal.—Liner President Taft went to Moore Shipyard for repairs to her machinery in excess of a cost of \$25,000. Work included retubing of her boilers and repairs to her condensers. Other work was on the main engines.

Reconditioning Steamer, West Coast.—A large sum will be expended in reconditioning the transport Sherman, purchased by the Los Angeles Steamship Company for \$60,000, for the Los Angeles-Honolulu run, to replace the City of Honolulu.

Repairs to British Schooner, Philadelphia, Pa.—Philadelphia Ship Repair Company was awarded a contract by T. H. Warren & Company to repair several bow plates and beams in the British schooner James William, damaged in collision.

Shipping Board Contracts, Maryland.—The Shipping Board awarded steamer Homestead to H. E.

Crook Company, at \$2,392, for repairs; and the steamship Chebaulip to the Maryland Dry Docks Company, at \$594, for docking for survey.

Steel Tug Hull, Midland, Pa.—Captain Oscar F. Barrett, of the Barrett Line, Cincinnati, O., let a contract to the Midland Barge Company, Midland, for the construction of a steel hull for a stern wheel towboat 175 feet long by 38 feet beam.

Two Contracts Awarded, Staten Island, N. Y.—Contracts for repairs to the steamship Charles H. Pratt and the steamship Baltic, both of the Standard Oil of New Jersey, were awarded the New York Harbor Dry Dock Company. Prices \$23,663 and \$12,060, respectively.

Contract Awarded, Mobile, Ala.—The Alabama Dry Dock & Shipbuilding Company has been awarded the contract for extensive repairs to the 1,133 net ton steam freighter Yumuri, of the Ward Line. The work includes extensive repairs to machinery and a great deal of hull work.

Contract Awarded, Mobile, Ala.—The United Fruit Company awarded a contract to the Todd Shipbuilding & Dry Dock Company, Mobile, for repairs, involving approximately \$50,000, to the steamship San Mateo. Work consisted of conversion from coal to oil burning and general repairs.

Contracts Awarded, Staten Island, New York.—The New York Harbor Dry Dock Company was awarded three repair contracts on Shipping Board vessels; two on the West Golomska and the other on the steamship Scottsburg. Prices were respectively \$2,620, \$2,648 and \$1,343.

Two New Ferryboats, Philadelphia, Pa.—Pusey & Jones Shipbuilding Company, of Wilmington, Del., has been awarded a contract to build two all-steel ferryboats for the Philadelphia & Reading Railway. They will be 200 feet long, and will ply between Philadelphia and Camden and will be the fastest ferryboats on the Delaware.

Jahncke Repairs, New Orleans, La.—Contracts recently awarded the Jahncke Dry Dock Company are as follows: Steamship Salaam, to undergo periodical surveys and minor repairs; Vaccaro Brothers' tanker Caloria, overhauled; Standard Oil tug Bonita, overhauled; and Magnolia Petroleum Company's barge Chagres, overhauled.

Extensive Overhauling, Eagle Harbor.—The motorship Coolcha, owned by the Pacific Freighters Company, went on the ways of the Winslow Marine Railway & Shipbuilding Company, Eagle Harbor, to undergo an extensive overhauling. The schooner Vancouver and the steamship Pacifico also went on the ways of the Winslow Marine Railway & Shipbuilding Company.

Miscellaneous Repairs, Mobile, Ala.—The Texas Company steamer New Jersey has been placed on the docks of the Alabama Dry Dock & Shipbuilding Company for repairs. The work included: renewing and hardening approximately one thousand rivets scattered about the shell; tanks; rudder arms and stern frame; number of plates faired and two coats of paint below light load line.

Construction of Tank Barge, Chester, Pa.—The Sun Shipbuilding Company received the contract for the construction of a twin screw Diesel propelled steel bulk oil barge for Standard Transportation Company of New York, subsidiary of the Standard Oil Company. Approximate total cost \$300,000. Dimensions, 254 feet length over all, 37 feet 6 inches molded beam and 14 feet molded depth.

Motor Schooner Drydocked, Mobile, Ala.—The Alabama Dry Dock Company was awarded the contract for repairs to the motor schooner Esperanza. The work consisted of the following: Cleaning, painting, repairs to damaged planking on port side forward, removing three sections of keel, renewing keel shoe, calking of vessel from keel to covering board, lifting and tightening of rudder, and painting bottom with copper paint.

Steamer Construction Contract Award, Bethlehem, Pa.—The contract for the construction of a new paddle wheel steamer for the Hudson River Day Line was awarded the Bethlehem Shipbuilding Corporation on a bid of \$742,140. Vessel was designed by J. W. Millard & Brother, naval architects, 17 State street, New York City. Dimensions are: over all length 333 feet, extreme breadth 76 feet and depth molded to main deck at side of guard 13 feet 8 inches.

Yacht Contract Held Up for Present, New York.—It is learned that the tenders received for the construction of a steel auxiliary schooner yacht, having a length of 125 feet and propelled by a 200 to 250

horsepower oil engine, for William P. Adams, of Chicago, have been set aside, the contract having been held up for the present at least. It is understood that the bids ranged from \$175,000 to \$375,000. The vessel was designed by Theodore E. Ferris, naval architect and marine engineer, 30 Church street, New York City, N. Y.

Alabama Dry Dock Work, Mobile, Ala.—Following contracts were awarded the Alabama Dry Dock & Shipbuilding Company: Texas Company's motor vessel Solitaire, to have bottom examined, both tail shafts drawn for inspection, strut bearings re-wooded, shafts replaced, minor leaks in way of engine room calked and made tight, pitted places on stern plates on both port and starboard sides built up by electric welding and to be painted; S. S. San Antonio, replacing of tail shaft and propeller; barge Oriole, voyage repairs.

Steamers Repaired, Mobile, Ala.—The following steamships have been awarded to the Alabama Dry Dock & Shipbuilding Company; stern wheel river steamer Volcano, operated in Mississippi-Warrior Service, for calking bottom, repairs to port rudder, repairs to machinery heater-pipe system, iron work on rudders, repair work about the cabin and installation of new radio room; Shipping Board steamship Braddock, for renewing several hundred leaky rivets in her bottom and considerable bulkhead repairs; Lake Gunn, for general repairs.

SHIPYARDS AND DRYDOCKS

Yard and Plant Improvement, Beaumont, Tex.—The Pennsylvania Shipyards, Inc., of Beaumont, Texas, formerly the Beaumont Shipbuilding Company, have completed their improvement to the old plant. They dredged a 28-foot channel to their docks and raised the fill about 6 feet to bulkheads, in all covering about 10 acres. The improvements include newly arranged and well equipped machine shop, plate shop, blacksmith and wood working shop. The 3,000-ton railway is complete and in operation.

PORT IMPROVEMENTS

Contract Awarded, New Haven, Conn.—New England Steamship Company, Bridge street, will rebuild dock on Bridge street, wood and steel. Price \$30,000.

Channel Improvements, Liberty, Tex.—District Engineer of Galveston is making plans for channel improvements from Liberty to mouth of Trinity River.

Terminals, Oakland, Cal.—The Southern Pacific Company, 65 Market street, San Francisco, Cal., has purchased 300 acres of waterfront land at Oakland, on which they will construct an extensive port terminal.

Contract Awarded, Kincardine, Ont.—Key Brothers, Kincardine, was awarded the contract to rebuild piers, stone and cement work, by the Department of Public Works, Ottawa, Canada. Engineer's estimate \$26,000.

Grain Elevator, Goderich, Ont.—Goderich Elevator & Transit Company, 85 Horton street, London, is having plans prepared for reinforced concrete grain elevator, along harbor; 1,000,000 bushels capacity; price \$250,000. Private plans.

New Dock, New Orleans, La.—Early next spring the Board of Port Commissioners of New Orleans will spend \$1,500,000 on the construction of a 2,000-foot modern shedded pier on the Industrial Canal, according to plans now being prepared.

Dock, Vancouver, B. C.—S. E. Junkins & Company, 837 Hastings street W., was awarded the contract for building a new dock 800 feet long, 333 feet wide, timber on creosoted piles or concrete slab on concrete piles (7,000,000 feet) by Canadian Pacific Railway, Seymour street. Price \$2,000,000.

Seawall, New Orleans, La.—New Orleans Levee Board, New Courthouse Building, plans 26,000 feet seawall from West End to Seabright, reclaiming 48,475,000 square feet of ground, of which 26,000,000 square feet will be devoted to public use, 4,495,000 square feet for streets and sidewalks, leaving

17,981,000 square feet for suburban development, including 70,200 cubic yards of reinforced concrete \$1,400,000, 560,000 feet creosoted piling \$252,000, lumber \$175,000, 750,000 pounds of iron and hardware \$22,500, and 16,262,500 cubic yards of hydraulic fill \$975,000.

New Pier, Hoboken, N. J.—Plans have been prepared for building of a new steel and concrete pier in Hoboken for the accommodation of the Leviathan, under supervision of Admiral W. S. Benson, Shipping Board Commissioner. Plans call for a double deck structure about 1,200 feet long and to cost between \$3,000,000 and \$4,000,000.

New Pier, Hoboken, N. J.—The contract for removing Piers 5 and 6 to make room for the new pier for the Leviathan was awarded to the Robins-Ripley Company, of 50 Church street, which estimates the cost approximately \$35,000. Dredging the slip to a depth of 45 feet will be done by the Morris & Cummings Dredging Company, of 17 State street, New York, for about \$60,000.

Harbor Improvements, Norfolk, Va.—United States engineer for rivers and harbors wants \$500,000 for new work on the Norfolk harbor during the fiscal year ending June 30, 1923, according to the engineer's report filed with Congress, December. The report shows that the completion and widening of the forty-foot channel from Hampton Roads to the Belt Line bridge will take the \$500,000 asked for. Other needed improvements asked for are: the inland waterway from Norfolk to Beaufort, \$500,000; dredging the forty-foot channel in Thimble Shoals from Hampton Roads to the sea, \$74,560; keeping of the channel of the James River at a minimum depth of eighteen feet and from 100 to 200 feet wide, \$40,000; improvement during the coming fiscal year in the Pagan River, \$2,000; and work on the Nansemond River to make it more navigable, \$42,000. This report goes into detail as to the waterborne commerce of Hampton Roads and its tributaries. The report goes into the history of harbor development here, also, and carries the figures all the way down the coast. It shows Hampton Roads as substantially a commercial leader. The total improvements asked for in this report amount to \$1,123,560, which includes \$500,000 for the Norfolk channel widening, the \$50,000 for maintenance work, and the \$74,560 for widening the channel at Thimble Shoals.

NEW INCORPORATIONS

The Royal Barge Line, \$750,000, incorporated in Delaware, to do business in barges.

The Coastwise Oil and Transport Company, Philadelphia, capital \$3,000,000, incorporated under Delaware laws.

The Motorship Transportation Company, capital \$10,000,000, incorporated in California, to carry fruits between Pacific and Atlantic ports.

The Sagadahoc Steamship Corporation, capital \$300,000, chartered at Albany. Incorporators: E. E. Baldwin, F. V. Barnes and R. F. Weeks.

The Bimini Steamship Corporation, capital of \$100,000, chartered under Delaware laws by John McGovern, E. Brouse and E. Levison, of New York.

King Boat Works, West Highlands, N. J., \$200,000, incorporated in New Jersey. Incorporators: George C. King, Harry N. Johnson, Leslie J. King and Stewart B. King.

Moore & McCormack Company have incorporated under Delaware laws for \$100,000 each the Commercial Traveler Steamship Company, Ltd., and the Commercial Spirit Steamship Company, Ltd.

GOVERNMENT WORK

Cranes, Puget Sound, Wash.—Specification 4753, Bureau of Yards and Docks, Navy Department, Washington, D. C., plans to purchase electric elevator cranes.

Extension to Dock, Boston, Mass.—Specification 5,753.—Bureau of Yards and Docks, Navy Department, Washington, D. C., plans extension to Naval drydock at Boston.

Contract Awarded, Beaver Falls, Pa.—The contract for the construction of three steel lump scows, bids for which were opened November 7, by the United States Engineer Office, Buffalo, N. Y., has been awarded the Penn Bridge Company, Beaver Falls, Pa. The company's price was \$92,120.

Contract Awarded, Gloucester, Mass.—Department of Public Works, State House, Boston, has awarded the contract to construct 1,008-foot granite faced concrete seawall, 47-foot concrete seawall, 76-foot granite seawall at Gloucester, to Bay State Dredging Company, 62 Condor street, East Boston (Boston P. O.); price \$54,630.

BUSINESS NOTES

Mr. A. A. Heller has taken over the management of the International Oxygen Company in place of Mr. L. W. Hench, secretary and general manager, resigned.

Mr. George Macnoe, Manager of the Boston Office of the W. B. Connor, Inc., has been recalled to New York to take charge of the Contractors' Sales Department, handling heating and pumping equipment.

Mr. A. E. Jones, sales engineer in the New York Office of the Terry Steam Turbine Company, has accepted a position with W. B. Connor, Inc., 90 West street, New York City, in a similar capacity. Mr. Jones assumed his new duties January 1, 1923.

The Wilson Welder & Metals Company is now represented exclusively in Maryland, Virginia and the District of Columbia, by the Alexander Milburn Company of Baltimore. A large stock of color-tipt welding metals and plastic-arc welding machines is available at this point for distribution throughout the territory and a complete demonstration plant is in operation.

The Roller-Smith Company, 233 Broadway, New York, N. Y., announces the appointment of the Electric Material Company as its agent in the State of Washington and parts of Oregon and Idaho. The Electric Material Company has recently opened an office in the Hincley Building, Seattle, and will handle the Roller-Smith Company's lines of electrical instruments, circuit breakers and radio apparatus in that territory. The Seattle office is in charge of Mr. R. F. Robinson.

The capital stock of the Southern Dry Dock & Ship Building Company, Orange, Tex., has been increased from \$100,000 to \$200,000, and all the new stock has been subscribed for. According to advices received, the principal business of the company has changed from shipbuilding to car building, hence the name has been changed in line with the greatest activities; namely, the "Orange Car and Steel Company." The personnel of the officers and management remains the same.

FOREIGN ACTIVITIES

New Dry Dock, Belgium.—The Belgium Government has allocated a sum of 13,000,000 francs for the construction of a new dry dock at Langerbrugge, near Ghent.

Order Placed, England.—Runciman & Company, of Newcastle, England, have placed an order for the construction of two large steamers with John Readhead of South Shields.

New Service, Germany.—The Hugo Stinnes Line has started a monthly service, with six new oil burning passenger and freight vessels of 9,000 to 12,000 deadweight tons, between Hamburg, Rotterdam, Dover, Antwerp and Naples and ports in China, Japan and the Philippines.

New Fireboat, France.—According to a report from the American Consulate, the Chamber of Commerce of Marseilles, France, has recently purchased a new fireboat, costing 400,000 francs, for the protection of the harbor. The new vessel has oil burning motors and can be set in motion at a moment's notice.

Commercial Harbor, Kiel.—The North Harbor of the port of Kiel, located on the Kiel Canal near the

Prince Henry Bridge, was inaugurated October 11, 1922. This small harbor, with a grain elevator of 12,000 tons capacity, is the first step in the realization of the many schemes to make Kiel a commercial port.

New Floating Dry Dock, Southampton, England.—Directors of the London and Southwestern Railway Company, which controls much waterfront property at Southampton, have sanctioned construction of a floating drydock at the port large enough to lift the Majestic. The new dock will be as large as those at Boston and Hamburg.

Contract Award, England.—Messrs. Vickers, Ltd., England, have been awarded a contract to build a new vessel for the Orient Steam Navigation Company. The ship will have a length between perpendiculars of 630 feet, molded breadth 74 feet and gross tonnage approximately 20,000. Her accommodations will include 600 first class and 1,300 third class passengers.

Oil Conversion, Nagasaki, Japan.—The Fukuoka Nichi Nichi reports that, according to information received at Moji and announced by the Department of Commerce, the Nippon Yusen Kaisha has adopted the furnaces of the Lisbon-Marú and four other steamers for the consumption of both coal and oil, owing to the cheapness of the latter. The Toba-Marú and Mayebashi-Marú had previously undergone similar alterations so that seven of the company's steamers are now capable of using oil or coal.

Dockyard Employees' Holiday, Nagasaki, Japan.—In order to avoid wholesale discharge of its employees at its shipyards at Nagasaki, the Mitsubishi Shipbuilding Company has inaugurated a system whereby its employees are compelled to take a week's holiday, in turn, during which time they are to be given 60 per cent or more of their wages. Men called upon to return to work for a short time during the holiday will receive a larger percentage of their pay, says Vice Consul Correll in a report to the Transportation Division of the Department of Commerce.

Contract Awarded, Scotland.—Messrs. Ramage and Ferguson, Ltd., Leith, were awarded a contract for an ocean-going motorship of large dimensions. The vessel will be approximately the same size as the largest motor yacht afloat, the Ara. She will be 200 feet long, propelling machinery will consist of two Sulzer Diesels each of 800 brake horsepower, driving twin screws. The engines will be of the normal two-cycle type fitted with port-scavenging, and will be of the same class as the Sulzer engines installed in many vessels of the Mercantile Marine. It is estimated that the fuel consumption will not exceed eight tons per day.

Official Trials, England.—The single screw cargo steamer S. S. No. 93, built by the London & Montrose Shipbuilding & Repairing Company, Ltd., for Messrs. Llewellyn, Merritt & Price, Ltd., of Cardiff ran very satisfactory official trials; the speed obtained being a knot and a half in excess of the contract. The vessel is of the raised quarter deck type with engines placed aft and is designed to carry 1,050 tons of cargo. She has been constructed for the owners special trade and her dimensions are 189 feet by 30 feet by 14 feet 6½ inches. The propelling machinery has been built by Messrs. William Beardmore & Company, Ltd., of Coatbridge.

Motor Vessel Launched, Greenock, Scotland.—The Drechtdyk, a large awin screw motor vessel built to the order of the Holland-America Line, was successfully launched from the Greenock Yard of Harland & Wolff, Ltd. The new vessel is a high class cargo boat 485 feet by 62 feet by 38 feet 6 inches with a gross tonnage of about 9,000. The total capacity of oil fuel tanks in the vessel is about 1,200 tons. A very complete outfit of derricks and winches is fitted to ensure expeditious handling of cargo. Steering gear, windlass and refrigerating machinery are all electrically driven. The machinery, which was constructed by Harland & Wolff at their Diesel Engine Works, Glasgow, comprises two sets of 8 cylinder 4 cycle Diesel engines on the well-known Brumeister & Wain system. The engines develop a normal horsepower of 6,000 indicated, at 115 revolutions per minute.

Steamer Launched, England.—A handsomely modelled steel twin screw steamer has been launched from the Neptune Works of Swan, Hunter, & Wigam Richardson, Ltd., for the Compagnie Generale Transatlantique, Paris, intended for their mail and passenger service from Le Havre and St. Nazaire to Colon and the Pacific. The steamer is about 495

feet long by 26 feet beam by 38 feet deep and is being constructed to the highest classification in the Registry of the Bureau Veritas. There are four complete decks besides promenade deck, boat deck and navigation deck. The vessel has all the latest improvements and carries first, second and third class passengers. The twin screw machinery, supplied by the builders, consists of two sets of turbines of the "Metropolitan-Vickers Rateau" type, with double reduction gearing of the three box floating frame type, steam being supplied by eight large boilers fitted with Howden's system of forced draft and arranged to burn coal and oil. As the vessel left the ways she was named Cuba.

Launch at West Hartlepool, England.—Messrs. William Gray & Company have launched the steel single screw steamer City of Singapore, which they are building for the Hall Line of the Ellerman Lines, Ltd., Liverpool. The vessel has a length overall of 451 feet, extreme breadth 57 feet 3 inches and depth molded 32 feet 10 inches, cruiser stern, and is classed 100 A-1 at Lloyd's. The ship is fitted out to meet the owners' special requirements for the trade in which she is intended to run, and the double bottom is arranged for the carriage of oil fuel and fresh water. The equipment embodies all the latest improvements, including fresh water distiller, steam windlass, steam steering gear, electric lighting and wireless installation. Propelling machinery, made by the Central Marine Engine Works of the builders, consists of a set of triple-expansion engines with cylinders 24½ inches, 42½ inches, 74 inches diameter by 51-inch stroke, and three large boilers adapted for a working pressure of 225 pounds per square inch, and fitted with Howden's system of forced draft.

Trial Trip, England.—The trial trip of the steamer Stad Haarlem, built by Messrs. Wm. Gray and Company, Ltd., West Hartlepool, and taken over by Messrs. Halcyon-Lijn, of Rotterdam, was very successful. The dimensions of the vessel are: Length overall, 321 feet 3 inches; breadth, 46 feet 6 inches; depth molded, 26 feet 3 inches, with a deadweight carrying capacity of over 4,800 tons. The Central Marine Engine Works built the propelling machinery, which consists of triple-expansion engines, with cylinders 25 inches, 41 inches, 68 inches diameter, by 45-inch stroke, and three boilers 13 feet 4 inches diameter, by 12 feet 2 inches in length, adapted for a working pressure of 200 pounds per square inch. An oil fuel burning installation is fitted, working in conjunction with Howden's system of forced draught. A large number of "CMEW" steamship auxiliaries are fitted, including auxiliary condenser, direct contact feed heater, evaporator, feed water purifying tank, main feed, centrifugal harbor feed, ballast, fuel oil, general service, and ash ejector pumps.

New Ship, Holland.—The Nederland Shipbuilding Company of Amsterdam, has signed a contract with British owners for the building of a tanker of 280 feet in length by 46 feet 6 inches beam and 19 feet depth. The vessel will be propelled by steam engines driving twin screws.

Tug Launched, England.—Messrs. John I. Thornycroft & Company, Ltd., have launched from their Woolston shipyard a powerful tug, built and engined for the Towing Department of the Southampton, Isle of Wight, and South of England Royal Mail Steam Packet Company, Ltd.

Successful Trials, England.—The trials of the Lochgoll, a large twin screw motor vessel of 5,500 tons, built by Harland & Wolff, Ltd., at their Govan Shipyard, for the Royal Mail Steam Packet Company, proved very successful. This latest addition to the company's fleet was built under special survey, and is classed 100 A 1, at Lloyd's. She has three complete decks with poop, bridge and fore-castle, her dimensions being 502 feet by 62 feet by 38 feet 6 inches. The steering gear, windlass and the 15 cargo winches are all electrically driven, and there are 33 derricks. The vessel is propelled by two 8-cylinder 4-cycle Diesel oil engines of Harland & Wolff's standard type, on the Brumeister & Wain system. These engines develop 6,000 indicated horsepower at 115 revolutions per minute and will give a sea speed of 12½ knots.

Maiden Voyage, Germany.—The Deutsch-Australische Line cargo steamer Kiel has left Hamburg, Germany, for her maiden voyage to Central America. Her dimensions are approximately 328 feet by 47 feet by 29 feet, with a hold capacity of 3,650 tons gross. The engines are triple-expansion, of 1,800 indicated horsepower, and are designed to steam at a speed of 10.5 knots. The vessel was launched at the Germania Yard, Kiel.

WE GUARANTEE that of this issue, 4,850 copies were printed; that of these copies 3,807 were mailed to regular paid subscribers, 393 were provided for counter and news company sales, 196 were mailed to advertisers, 81 were mailed to employees and correspondents and 373 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 9,850, an average of 4,925 copies a month.

MARINE ENGINEERING AND SHIPPING AGE is a member of the Associated Business Papers, Inc. (A. B. P.), National Association of Periodical Publishers, Inc., New York Business Publishers' Association and the Audit Bureau of Circulation (A. B. C.).

Requests for change of address should reach us two weeks before the date of the issue with which it is to go into effect. It is difficult, and often impossible, to supply back numbers to replace those undelivered through failure to send advance notice. In sending us change of address, please be sure to send us your old address as well as the new one.

Don't Give Up The Ships

AT about the same time that Captain Lawrence gave his famous command "Don't give up the ship" a certain general whose name is best forgotten gave the following order to the American army defending the city of Washington: "If you retreat, go by the way of Georgetown." Needless to say the army went that way allowing the British that entered the city to disgrace themselves by burning our public records and buildings.

In those days we were a maritime nation; we had more sailors on our ships than we had soldiers in the army, and every sailor was well aware when he entered an engagement that it was a case of victory, surrender or death. Did Commodore Perry have any thought of giving up when his flagship was sinking? No, not so long as a rowboat was available to take him to another vessel and to one of the most glorious naval achievements ever accomplished.

Strange as it may seem we are now in the midst of a fight upon the result of which depends the very existence of our commercial and naval power. Ignoring the teachings of all history, that a non-maritime nation cannot maintain its place, even a number of those engaged in the shipping industry are accepting what one of our esteemed contemporaries aptly calls "defeatist propaganda" and are preparing gracefully

to retreat along the road of continued Government ownership.

Under Government ownership only 386 vessels out of a total of 1,379 are in operation and thus it is costing the taxpayers \$50,000,000 annually to keep a ratio of about one in four of its vessels working. Some of our senators seem to believe that it is more desirable to keep up this tragic situation rather than allow a subsidy of from fifteen to thirty millions for the purpose of interesting private capital in taking over these ships and operating them on sound business principles.

Now is the time for every man engaged in the maritime industry to write to his senator and to let it be known to all his associates that no constructive alternative to the Administration's shipping bill has yet been proposed. Practically all of our senators want to see our merchant marine developed. They are open to argument and example and, if this is not forthcoming from shipping men, who will furnish it? Watchful waiting may be advisable in some matters but a "we have just begun to fight" policy is more in accord with our marine traditions and certainly more likely to secure the respect of our senators. As Congressman Scott of Michigan recently said, "Two things are required to secure legislation, necessity and demand." The necessity for an adequate merchant marine exists but the demand is not strong enough.

The Navy Needs Ships and Men

THE Navy needs to have a number of its capital ships modernized, it needs fast scout cruisers of the 10,000-ton type permitted by the Disarmament Conference, it needs destroyer leaders and it needs aeroplane carriers. If the people of this country are not to be deceived about the relative strength of the Navy, a constructive program should be started at once, for the 5-5-3 ratio under present conditions is nothing less than a joke.

We not only need more ships to balance the fleet as compared with other powerful navies, but we need more men. Congress allows a personnel of only 86,000 men as compared with England's 120,000. Our enlistment period is only four years as compared with twelve years in England. Our enlisted personnel is largely composed of boys who serve only one term, whereas men who have spent twelve years at sea usually remain. Almost every trade is represented on a capital ship, and the majority of the crew of these complex fighting machines should be skilled mechanics. Is it not a terrible responsibility for this country to allow a condition to arise where it might be necessary to send these ships into

battle manned by untrained men? After agreeing to scrap over \$300,000,000 worth of capital ships and fixing on a definite naval strength, why not live up to it? Other countries will never sign on the dotted line again if we don't.

Immigration Should Be Selective

INDICATIONS that there will be a shortage of labor in our large industries have awakened discussion on the possibility of revising our immigration laws. The present law limits the number of aliens that may enter this country in any one year to three percent of the number of their fellow countrymen that resided here at a particular time.

As is well known, this law has worked severe hardships not only on the steamship companies but also on the im-

any requirements as to character or mentality that we specify. Canada is basing its immigration regulations on the selective system and we would find it both practical and advantageous to follow her example.

The Passing of the Minnesota

THE *Minnesota*, the largest merchant ship ever constructed in an American shipyard, the largest vessel in deadweight carrying capacity afloat today (22,500 deadweight tons) and, at the time her keel was laid in 1901, the largest vessel either built or building in the world, is to be broken up on account of her age and lack of ability to make an economical speed. The passing of this vessel ought to be a great object lesson to every American, for when James J. Hill built the *Minnesota* and her sister ship, the *Dakota*, he probably firmly believed that the country would enact legislation granting a reasonable subsidy to American ships.

Although several attempts were made to secure Government aid at that time, they all failed but the last bill was defeated in the House of Representatives by a margin of only 3 votes. Not only this, Mr. Hill was prevented in many other ways from making these vessels a financial success in the Seattle-Orient trade. Their splendid passenger accommodations and their enormous cargo carrying capacity should have been of great value to the Great Northern Railway and the producers of the whole country, but the Interstate Commerce Commission would not allow an export rate over the railroads that would permit a fair return to the steamship line. To cite a specific instance, Mr. Hill planned to take cotton from Louisiana by rail to Seattle and then ship it to the Orient. He could have done this successfully but the Government would not allow him to charge less for the rail rate to Seattle than the domestic rate to an intermediate point.

It is well known that both Messrs. Harriman and Hill were deeply interested in promoting American steamship lines on the Pacific and it is a great tribute to Mr. Hill's vision that he started to build, over twenty years ago, practically the type of combination cargo and passenger ships that have been adopted in the post war designs of the leading English steamship companies. In fact except in the matter of speed he is still in the lead; for with the exception of a few giant passenger liners in the North Atlantic service it is recognized that the combined passenger and freight vessel is the most economical type today. Compare one of the latest Cunarders, the *Scythia*, with her gross tonnage of 18,500 and her speed of 17 knots, with the *Minnesota* whose gross tonnage is 20,602 and her designed speed 14 knots.

What a shame that the foresight of this great man was not backed up by the Government; for, if he had received any encouragement, he and others would have built more vessels and we would not have been caught in anywhere near so badly an unprepared state when the war came.

However, the past is past, we still have men of broad vision and we also have a wonderful example of what can be done by the coordination of a great railroad and steamship line. If the Canadian Pacific Railroad can operate a splendid steamship service on both the Atlantic and Pacific in connection with their railway system, why cannot we follow their

The Goose With the Golden Eggs

—McCay in the *New York American*.

migrants themselves and has led to a condition where a few hours' difference in the time of arrival of a vessel is often the determining factor of admittance. Would it not be of far greater advantage to us to place a limitation on the quality rather than number of immigrants? Is it not the anarchist rather than the producer which we desire to exclude or have we reached the limit of the industrial expansion that has made this country great? We believe that there is still room for the class of foreigners who will make good citizens and that the cooperation of the steamship companies would be gladly offered to secure such results.

The Red Star Line, for instance, has been in business for fifty years, its agents go into every country and they know all races and every grade of society. In other words this company must know exactly who they are forwarding and further they have every means of testing the mental and physical condition of their prospective passengers at the port of embarkation. This and many other companies could easily meet

lead? By no means the least important provision in the pending shipping bill is the clause permitting the intimate co-operation of rail and water transportation. The responsibility for the future is now squarely up to the United States Senate.

Cooperation Along Atlantic Seaboard Proposed

THE New York Board of Trade and Transportation has appointed a special committee of which W. T. Donnelly is chairman for the purpose of bringing into existence a clearing house in New York for trade and transportation problems of the Atlantic Coast states. Mr. Donnelly has cruised along the seaboard in his yacht from Maine to Florida and has talked to the business men and commercial bodies in most of the seaports.

As a result of this investigation he has found that every city has its transportation problems and that they are fundamentally of the same general character. The larger and unsolved problems of these seaports are of such a nature that they can only be properly handled by a central committee of able engineers whose services can be most easily obtained in a central location like New York.

While some of the people in the Southern seaports are more or less inclined to look at any project coming from New York City with suspicion nevertheless the fact that engineering skill and transportation of their agricultural products by water highways would create a market for their fruit and vegetables such as we are now importing from South America is bound to receive favorable consideration.

Great areas of the most fertile land in the country now lie under water in these areas and they can be reclaimed so that they will produce foodstuffs cheaper and in closer proximity to cheap transportation than any other section. In fact, there is an opportunity to repeat exactly what has been done in Holland which has furnished England with cheap produce for over three hundred years.

Standardization of German Shipbuilding

THROUGH the courtesy of the Transportation Division of the Department of Commerce we are able to publish the following report of the American Consul at Hamburg, Germany, relating to the progress made in the standardization of ship parts in that country.

"Standardization of German shipbuilding began in November, 1916, when the late marine engineer Veith called a meeting with a view to establishing a Marine Standardization Commission (Marine Normen Commission). This meeting took place on November 18, 1916, at the Germania Wharf, Kiel, and was attended by the representatives of the German Navy and merchant marine. Sitzings were held periodically until the end of the war, when they were discontinued.

"The success which attended the work of this commission was an inducement to establish a similar organization to take care of the present day German merchant marine shipbuilders. This commission, known as the Handels Normen

Ausschuss, is composed of representatives of five of the most important shipping companies and by the representatives of ten of the largest shipyards.

"Up to the present time a total of 1,026 standard parts has been passed by the commission and a number of ships have been provided with parts manufactured according to its standards.

"Quite recently, the Handels Normen Ausschuss, which followed the work of the Marine Normen Commission, had

Looks like a lot of money to pay for medicine—

But it isn't half as much as the undertaker will charge
Cheaper to Pay the Doctor Than the Undertaker

—Darling in the New York Tribune.

an exhibition in the Charlottenburg Academy showing a collection of parts which were manufactured according to the new marine standards. About 50 firms from all parts of Germany sent exhibits.

"This is the beginning of a new epoch in shipbuilding which all countries having a merchant marine may advantageously adopt, thus greatly facilitating the building and operating of ships. This is an extremely favorable economic procedure which railroad companies have long since followed and which has proved so beneficial that it is to be wondered at that the standardization of parts for ships did not spread to the shipbuilding industry in all countries a long time ago."

East Versus West on the Shipping Question

Lack of Understanding of Natural Significance of American Merchant Marine Shown in Arguments of Opponents to Subsidy Bill

By C. A. McAllister

THE writer recently published an article on the "A B C of the National Shipping Bill," in this magazine, which was subsequently reprinted in pamphlet form and given wide circulation. A copy of this was forwarded to a banking friend in Chicago, which brought forth the following reply:

"Chicago, Ill., December 20, 1922.

"My dear Captain:

"I acknowledge receipt of a reprint of your article recently published in MARINE ENGINEERING AND SHIPPING AGE entitled 'A B C of the National Shipping Bill.'

"I have read this with much interest and I congratulate you on the simple and able way in which you present this subject from your viewpoint, even though I fear I cannot agree with all of your arguments and certainly not with all of your conclusions.

"Many of us in the West, including the writer, are opposed to a national subsidy to promote American shipping, believing that this is wasteful and uneconomic in principle. I think that our opposition is chiefly based on the theory that if foreign ships can and will carry our products cheaper than we can carry them, we should permit them to do so and that there is no good reason why we should spend public money to foster an enterprise which can be more economically handled in, by or through other countries. In other words, if a United States marine can handle shipping as cheaply as foreign vessels, then there is no need for a subsidy and if they cannot handle the business as cheap as foreign vessels, it is wasteful and uneconomical in principle to attempt to engage in that line of business.

"Personally, I see no particular advantage to a United States merchant marine and we have gotten along pretty well for a good many years without anything of that kind worth speaking of. So far as future wars are concerned, it seems highly improbable that there can be any important war for many years to come, owing to the terrific exhaustion of a large part of the civilized world in the recent conflict. Moreover, it seems to me altogether probable that if there should be another great conflict in the distant future, fighting apparatus would be so changed that a merchant marine on present-day lines would be of little or no practical use.

"Your argument intimates that ship subsidies will probably be unnecessary after 10 years. I disagree on this point and believe that a subsidy will always have to be paid in order to maintain a United States merchant marine. We had a considerable merchant marine, something like a hundred years ago, without any subsidies whatever and this instead of growing, developing and increasing, gradually disappeared under adverse economic influences which still exist. These adverse influences would operate in the same way now to prevent any American merchant marine from being self-supporting, and, if subsidies were discontinued at the end of 10 years, the American merchant ships would again disappear from the ocean. The whole question seems to me to be an unwise attempt to spend the public money in defiance of economic laws.

"Referring particularly to your argument respecting the way in which the building of American ships will benefit labor, I should think it were quite apparent that we haven't sufficient labor in the country now and that there is no occasion for diverting one hundred thousand able-bodied American laboring men from other useful and productive en-

terprises into the unproductive shipbuilding business. So far as the American farmer is concerned, these men will have to be fed in any event, whether they are engaged in shipping, building or in the steel industry and the connection of their employment could have no effect on the prices of farm products.

"If a United States merchant marine cannot stand on its own foundation it ought not to exist. To support it by special subsidy is merely to waste public money which has to be raised by taxation and additional burdens in other enterprises. We have already wasted a great deal too much.

"Cordially yours,

"L. ———."

The above letter represents the opinion of a number of our prominent business men in the Middle West but the fallacy of such arguments is apparent to those who understand the importance of an American merchant marine as shown by the following reply:

My dear L.:

I have your very frank criticisms of my views on shipping legislation, and am indeed glad to receive them, as they represent in very straight-out terms a sentiment confined largely to the Middle West, but which has been, thus far, sufficiently potent to delay action on this very important bill.

OPINIONS INFLUENCED BY GEOGRAPHIC ENVIRONMENTS

In a vast country like ours differences of opinions on great economic subjects such as this, are bound to obtain, influenced largely, I think, by geographic environments, which cause us to view this and kindred subjects from entirely different viewpoints. Indeed so antipodean are the opinions of Americans on many of our economic problems that it is quite remarkable that there is concert of action on more than the most elementary principles of self-government. It probably is due solely to the underlying American trait of fairness that, as a nation, we have gotten together after full and free discussions and enacted many of our laws for the general good. That we have prospered far beyond the most sanguine dreams of the founders of the Republic, must be taken as evidence that most of our laws have been beneficial.

In making the following replies to the several criticisms which you have made, I do so merely to point out wherein our differences of viewpoints lead us, and their direct bearing on the prosperous conditions which this country has developed.

Your statement that "I think that our opposition is chiefly based on the theory that if foreign ships can and will carry our products cheaper than we can carry them, we should permit them to do so," and that "there is no good reason why we should spend Public money to foster an enterprise which can be more economically handled in, through or by other countries" is one that is really the heart of the entire controversy between East and West.

FALLACY OF ALLOWING FOREIGN SHIPS TO CARRY OUR PRODUCTS BECAUSE THEY CAN DO IT CHEAPER

This argument is certainly not new as it has been raised against every new industry in which this country has ever embarked. Fortunately for all concerned it has but seldom prevailed.

If it had been carried out logically from the beginning

of our national life, we would today be a nation of producers of raw materials, with just sufficient mercantile and banking interests to carry on the exchange of these raw materials for the manufactured articles of Europe. For example iron and steel are the great basic materials on which our predominance as a manufacturing country depends. In the early days we could not produce iron or steel goods of as good quality or anywhere nearly so cheaply as we could purchase them abroad and have them delivered at our very doors. Our English cousins were quite willing and anxious to make all our iron products for us, and even went so far as to tell us that it was "wasteful and uneconomic" for us to embark in that enterprise which they could do for us so much cheaper.

THE CASE OF TEXTILES

In the great cotton industry they welcomed the raw product, which the fertile soil of our Southland produced so lavishly, but our early New Englanders, while familiar with spinning jennies, should never go into the manufacture of textiles because the mills of Manchester could do it so much better and cheaper than they.

In our own generation we have seen the great advances made in the manufacture of woollens in this country. Why should we have ventured into that industry at all? English mills made splendid cloth, and sold it to us much cheaper than we could produce it here. We also have seen the rise of the tinware industry in this country. As boys we remember when all such was imported from Great Britain. Why should we not have continued to buy it abroad? They made it cheaper than we could here, and cheaper even now than we can make it. Apply the same reasoning to any one of our great manufacturing industries in this country and you will find that almost without exception none has been built up without being fostered by our Government through the medium of the protective tariff.

SUBSIDY SERVES AS PROTECTIVE TARIFF

Now this proposed payment to shipowners, popularly known as a "subsidy," is nothing more nor less than a protective tariff to shipping; as it is the only industry in this country today which does not have protection of some sort why single out this oldest of all industries, as the only one which must alone and unaided wrestle with our old friend "economic conditions"?

So much for the fairness of the proposition, let us now look at the subject as a matter of self interest to the nation, and consider your statement that "I see no particular advantage to a United States merchant marine."

Your great city of Chicago has been built up from a trading post where the farmers of the vicinity swapped their raw materials for the clothing, furniture, hardware, etc., necessary for their existence, which had been brought by ships from European manufacturers, into one of the greatest manufacturing centers of the world, largely through the benefits of the protective tariff, and through its contiguity to the products of farm and mine. You are prosperous just now, because the United States is prosperous and consumes the bulk of your manufactured output, the remainder going to devastated countries in Europe, where the demand is strong and the buying power weak. If the home markets could take all your output, all well and good, as your only need for shipping would then be the modern prairie schooner running on steel rails.

But Germany and Russia are not going to remain out of the economic picture all the time, and when they get back to producing and trading, Chicago and the Middle West will not find such easy world markets for their excess products of the farm and factory. Germany showed quite conclusively that by her cheap manufacturing and owning her own merchant ships she was very rapidly assuming mastery of the world's commerce, before her militaristic leaders led her

into national hara-kiri. Her commercial supremacy was, as every one knows, built up almost coincidentally with and principally due to the upbuilding of her merchant marine.

COMPETITION IN FOREIGN MARKETS

When world conditions grow normal, as they must, we will have at least a surplusage of fifteen percent of farm and manufactured products, which we will have to sell in competitive markets abroad. In spite of your dictum that the ship which will carry our exports the cheapest should get the business, you know full well that the oft pronounced adage that "you cannot sell your products from the other fellow's delivery wagons," applies just as forcibly to our world trade, as it does to small town rivals in merchandise. Human nature prevails throughout all our undertakings, no matter on how large a scale transacted. You cannot expect an English or a German ship to carry goods manufactured in Chicago to a competitive market in South America for example, and not give preference in the many ways known to ship operators, to similar goods manufactured in their own countries which are in the competition. To illustrate, I must quote an incident which actually occurred in one of the leading ports of South America.

A large railroad contemplated the purchase of thirty locomotives, and invited bids from builders in the United States, England and France. An English attaché of the consulate, and they are always on the alert, persuaded the purchasers to change the proposals from f. o. b. nearest seaport to c. i. f. The bids when received were so close between American and British builders, that the decision was made on the difference in the cost of the freight. It happened that the same British steamship line served both Liverpool and New York from this South American port, and, although New York was actually 500 miles nearer the point of destination, the American locomotive builders were quoted higher rates than the English builders. This resulted in a contract involving over half a million dollars being given to Great Britain instead of to us. Oh! yes! Let the "cheapest" carrier do our business for us.

Again, it is a well known fact that British ships carrying our cotton to their own ports have actually carried their manufactured articles on the return trips to what should be our natural market, ports in the West Indies, at a lower rate, than they could be carried in "foreign ships" from Boston and New York. How could they do that, I hear you ask? Very simple, they "stung" our Southern cotton growers a sufficient excess in freight on their home-bound voyages to make the round trip profitable. Yet the Southern representatives in Congress are joining you people in the Middle West in damning anything which helps an American merchant marine.

Once more, "let the cheapest carrier do our business."

IMPORTANCE OF A MERCHANT MARINE TO THE NATION

In the arguments which you and the other opponents of American shipping put up, you overlook the great underlying fact that a merchant marine must be national, just as much as the Army and Navy. There are certain functions in life, which we as individuals, families, cities, states or as a nation must do for ourselves; things which we cannot hire done by others, even though performed cheaper. Now I haven't a doubt in the world but what we could replace all the officers and men in our Army and Navy by officers and men from Germany or Japan, and have both these great services run "cheaper" than they are now. I also have no doubt, but that the city of Chicago could go out to India for example, and employ big, lunky natives to serve you as policemen and firemen, for less than half the present cost to Chicago taxpayers of your present efficient forces.

On your principle of having the merchant marine "more

economically handled in, by or through other countries," just begin at home by applying that principle in the direction I have suggested, and see what would happen. The "economy" would be there, but, Oh Boy, what a ruction would be raised! You see these grand and glittering economic generalities do not work so well, when generally applied. Therefore, to use the language of the day "Why pick on us?" Why pick on an industry which has built up all the great nations in history, because shipping is most decidedly a *national* institution.

UNJUSTIFIED OPTIMISM

Referring to your optimism regarding the improbability of any important war for many years to come, and hence no necessity of a merchant marine for military purposes, I must say that I devotedly join with you in your *hopes* along that line. Just as I am writing this, however, I note that a vast French army is marching into Germany. Evidently the dove of peace in that locality is getting his, her or its feathers scorched.

It was just such optimism as you express, and which was enunciated by millions of our countrymen, which led us to neglect our merchant marine for over half a century. The net result is that you and I and all our fellow long suffering taxpayers will be digging down in our threadbare jeans for the next fifty years or more, to pay our portion of the annual interest on about three billions of Liberty Bonds, being the amount we very feverishly expended to build up our merchant marine in two years' time, to meet the conditions thrust upon us in a World War, which optimists thought would never come upon us.

I am just as far from being a militarist as are you, and I cannot conceive of anything being more wasteful, uneconomical and suicidal than this continued wrangling between nations, with resultant squandering of money for military purposes. But I am old enough to have observed that human characteristics have not changed appreciably in my lifetime, and show no evidences of even changing for the better. So long as individuals will quarrel and fight, what can we expect of nations composed of individuals possessing and governed by fundamental human traits. Under such conditions the best we can do is to prepare for the worst that can happen, and feel quite sure that our very preparedness will do more to obviate armed conflict than any other precautions we can take.

MERCHANT SHIPS WILL BE NEEDED FOR FUTURE WARFARE

As to your surmise that future warfare, if it should occur, would be conducted with such new apparatus as to preclude the use of a merchant marine, let me suggest that mankind has not yet mastered the art of walking on the water to any considerable extent. If the scene of future hostilities is transferred to the air, as I firmly believe will happen, supplies and men will still have to be transported over the seas in merchant ships and transports. I cannot conceive of any kind of warfare being carried on, where the use of ships on the surface of the seas will not be necessary. Ships capable of going to sea in all kinds of weather cannot be improvised nor purchased from other nations after hostilities have commenced. If we are again caught without sufficient merchant shipping as we were during the recent war, our penalties may be far greater than those from which we are now suffering, in the form of our great national debt. We too may be confronted with reparations in addition to our own debts, as it is quite conceivable that the next time we will not have self-interested allies to make up our deficiencies on the seas.

If you will read President Harding's able message on our present shipping status, it will be very plainly proven to you that the passage of the pending bill will actually decrease our present taxation instead of increasing it, as is

popularly supposed by those who have given the subject only superficial study.

Thanking you for the attention you have given my brief on the subject, and the opportunity of making this reply, I am,

Cordially yours,

C. A. McALLISTER.

Diesel-Engined Combination Lighter and Towboat Ordered

A CONTRACT has recently been awarded by the Cuban-American Sugar Company to the Vinyard Shipbuilding Company, Milford, Del., for a combination lighter and towboat, designed by Cox & Stevens, naval architects, New York, who will also superintend the construction of the vessel.

The boat, which will be equipped with a Diesel motor, is of wooden construction of the following dimensions:

Length overall	90 feet, 0 inches
Length on waterline	85 feet, 6 inches
Breadth molded	22 feet, 0 inches
Depth (top of keel to top of deck beam at side) ..	10 feet, 10 inches
Draft	8 feet, 0 inches

The boat is of the conventional lighter type, with machinery aft, derrick mast and boom at the forward end of the house, and a cargo hold forward, as well as stowage for deck freight. The scantlings of the hull are in accordance with best practice for vessels of this type. Particular attention has been paid to fastening the hull so as to secure rigid construction, the planking having square fastenings with two locust treenails and two galvanized iron spikes to each frame crossing.

Water tanks of galvanized iron construction of 500 gallons capacity are provided under the after deck, and fuel oil tanks of three tons capacity, lubricating oil tanks of 120 gallons capacity, as well as tankage for kerosene and gasoline are provided, all of steel construction except the gasoline tank which will be of copper.

The machinery equipment consists of the main engine of the Winton Diesel reversible type, to deliver 225 brake horsepower, with air compressor, fuel oil service and transfer pumps, and all the necessary equipment for complete installation. Electric lighting will be supplied by a 5 kilowatt Winton generator set, using kerosene as fuel. There will be a hoisting engine, oil engine driven. Steering will be by hand from the pilot house.

In the house on the main deck there will be forward of the machinery enclosure a double-bedded stateroom, on the port side of the engine room enclosure another stateroom with two berths, opposite which on the starboard side is a toilet and a stateroom. Aft of the machinery space and in the same house on the port side is a galley, fully equipped, and on the starboard side a mess room for the crew.

On top of the deckhouse between the funnel and the mast is a pilot house with a berth for the captain.

The after deck is left clear for towing purposes and is fitted with heavy towing bitts. A cargo winch is placed aft of the mast, the upper deck being carried over at this point to afford protection from the weather. The whole deck forward of the house is left clear for the stowage of cargo. Forward on the centerline is a heavy pair of bitts of the regular towboat type, and all the necessary and usual chocks and cleats and deck fittings are included in the specifications.

It is interesting to note that on this small craft it will be possible, even when water and fuel tanks are full, to carry approximately 100 tons of cargo. This would have been an impossibility on the given dimensions had steam machinery been employed for an equivalent steaming radius.

Effect of Stevedoring Costs on Operating Expenses

By Lawrence B. Chapman*

Discussion based on theoretical ships, ideal trade conditions and certain assumed data showing what gains in profits may be expected by reduction in stevedoring rates and quicker turn-arounds.

TODAY a great deal of attention is being directed to the handicap of American ships because of the greater first costs and higher wages and subsistence costs of American crews. Fuel costs, engine-room economy and the advantages of the motorship are also receiving much attention. While all of these are important in the building up of an efficient merchant marine in competition with other nations, yet it is interesting to note that practically no attention is being directed at the problem of cargo handling and turn-around. It is obvious to even the casual observer that most of the methods used today in handling cargo at American ports are very inefficient and slow. The problem of handling of ship's cargoes is intimately connected with the layout and operation of marine terminals and piers and one should not be studied without attention to the other. However, it is my intention to take up at this time only one phase of the problem, namely, the loading and unloading of the cargo at the ship.

COSTS OF LOADING AND UNLOADING CARGO

The costs of loading the cargo from the pier to the ship's hold and discharging the cargo from the ship to the pier rightly belong to the operating charges of the ship; while the handling of the cargo to and from the transit shed, sorting, tiering, etc., should be charged against the cargo and not against the ship. To show the effect on operating expenses of cargo handling and turn-around the following example is given. This example assumes ideal conditions and speeds of cargo handling beyond present day practice. It is presented to illustrate how variations in the speed and cost of handling cargo affect the annual profits.

MAIN PARTICULARS OF VESSEL

Length between perpendiculars.....	420 feet
Beam	60 feet
Draft	26 feet

*Head of the Course in Ship Construction and Marine Transportation, Lehigh University, Bethlehem, Pa.

Depth	35 feet, 6 inches
Displacement	14,600 tons
Gross deadweight	10,000 tons
Net cargo deadweight for 5,000 miles.....	9,050 tons
Net tonnage	4,750
Sea Speed	11½ knots
Shaft horsepower	2,980
Gearred turbines; watertube boilers; fuel oil; cargo carried per voyage.....	75 percent of net cargo deadweight
Initial cost of ship.....	\$1,000,000

Table I gives the data and annual operating expenses for the above ship for four different conditions of cargo handling. The data for ship No. 1 is taken with a slight modification in fuel cost from an article by the author in the January issue of MARINE ENGINEERING AND SHIPPING AGE. The reader is referred to that issue for a full explanation and method of computing the data.

In computing the expenses shown in Table I it was assumed that 5 hatches were in operation for 10 hours per day and that each hatch was handling 30 tons of cargo per hour—a rate very much higher than the average today.

RATE OF STEVEDORING

Observations by the author at the Port of Boston over a period of two months covering a large number of ships with a great variety of cargo, brought out the fact that the average speed of handling cargo was about 20 tons per hatch per hour with about 25 tons per hour as a maximum. These observations also showed that in most cases only three hatches were being worked at one time. This would give a rate for the ten hour day of 20 x 3 x 10 = 600 tons per day instead of 1,500 tons per day allowed in Table I for ship No. 1.

The writer has observed many cases where the rate has been as high as 32 tons per hatch per hour for short periods. In one case where sugar was being unloaded the rate averaged nearly 70 tons per hatch per hour for a long period. The rates used in Table I have purposely been chosen in

TABLE I.—DATA FOR VOYAGE OF 5,000 MILES

	No. 1	No. 2	No. 3	No. 4
1. Rate of stevedoring (tons per hatch per hour).....	30	20	30	30
2. Hatches being worked.....	5	3	5	5
3. Rate of stevedoring per 10 hour day (tons).....	1,500	750	1,500	1,500
4. Cost of stevedoring per ton handled.....	\$.70	\$.70	\$ 1.40	\$.35
5. Calculated days on the run + 5 percent.....	19	19	19	19
6. Calculated days in port + 10 percent.....	10	20	10	10
7. Days per single trip.....	29	39	29	29
8. Single trips per year.....	11.53	8.60	11.53	11.53
9. Tons carried per year at 75 percent capacity.....	78,300	58,300	78,300	78,300
Annual expenses:				
10. Depreciation (5 percent).....	\$50,000	\$50,000	\$50,000	\$50,000
11. Insurance on hull and machinery (5 percent).....	50,000	50,000	50,000	50,000
12. Repairs, maintenance and overhauling (5 percent).....	50,000	50,000	50,000	50,000
13. Fuel used at sea and in port at \$1.25 per barrel.....	72,500	59,000	72,500	72,500
14. Lubricating oil and fresh water.....	3,000	3,000	3,000	3,000
15. Wages of crew.....	37,500	37,500	37,500	37,500
16. Subsistence	8,500	8,500	8,500	8,500
17. Tonnage dues and port charges.....	34,500	39,500	34,500	34,500
18. Brokerage and management.....	39,000	29,000	39,000	39,000
19. Stevedoring	110,000	81,500	220,000	55,000
20. Annual operating expenses.....	455,000	408,000	565,000	400,000
21. Receipts from cargo at \$7.50 a ton.....	586,000	438,000	586,000	586,000
22. Annual profit (Line 21—Line 20).....	131,000	30,000	21,000	186,000
23. Percent return on investment.....	13.1	3	2.1	18.6

excess of rates used today to show the effect of quick turn-arounds on profits and freight rates.

Anderson in his paper "The Most Suitable Sizes and Speeds for General Cargo Steamers" before the Institution of Naval Architects in 1918 proposed rates for a ship of this size of 36 tons per hatch per hour. He assumed 6 hatches in operation for 10 hours giving 2,160 tons per day as an ideal condition of cargo handling.

BASIC COST OF HANDLING CARGO

The basic cost of handling cargo has been taken as 70 cents per ton and calculations have been carried through for rates of one-half and double this basic rate. Two rates of cargo handling are given, namely, 1,500 tons per day and 750 tons per day.

Table I shows the total annual operating expenses and profits for a freight rate of \$7.50 per year for four different conditions. The data in this table bring out some interesting facts.

DAYS SPENT IN PORT PER VOYAGE

Line 6 shows the days spent in port per voyage discharging and receiving cargo. This time is directly affected by the rate of stevedoring. The result of reducing this rate for ship No. 2 doubles the number of days spent in port and reduces the number of trips per year. This in turn reduces the income from cargo (line 21) and the annual profit (line 23).

For ships Nos. 3 and 4, when the rate of handling cargo remains the same as for ship No. 1, the only item changed is the cost of stevedoring (line 19). The effect of this on the profits is shown in line 23.

The capital charges, which are 15 percent of the investment, continue whether the ship is in port or at sea. As the ship is built primarily to carry cargo between two points, its efficiency should be measured by the percentage of the total time that is spent at sea. For the ship in question, the capital charges amount to \$410 per day. If the ship is idle, this item is a dead loss, for the ship is not earning profits while in port.

The calculated time in port for cargo handling has been increased 10 percent to allow for tides, holidays, etc., and the calculated time at sea has been increased 5 percent to allow for bad weather. Thirty days per year have been allowed for annual overhauling. The crew's wages are based on the Shipping Board's scale effective April, 1922. Fuel oil has been assumed at \$1.25 per barrel and 8 pounds per gallon, lubricating oil at 75 cents a gallon and feed water at \$1 a ton. Port fuel for heating, lighting and operating the winches is 7 tons per day. Port charges include tonnage dues, pilotage, towage, miscellaneous fees, cooperage, dunnage, watchmen's and clerks' wages and wharfage.

VARIABLE FACTORS AFFECTING STEVEDORING COSTS

The data presented in the tables are for a voyage of 5,000 miles and the stevedoring costs naturally vary with the length of voyage. For this same ship on a voyage of 10,000 miles the number of trips per year becomes 7.15 and the cargo carried per year reduces to 43,000 tons. Thus on the long voyage the stevedoring costs are reduced because of the smaller number of tons handled per year. For ship No. 1 the stevedoring charges reduce from 24 to 15 percent of the total operating expenses for the 10,000 mile voyage.

Conversely, the shorter the voyage the greater are the relative charges for stevedoring, becoming an extremely large proportion of the operating expenses of the vessel on the very short route.

The cargo handling charges also change with the size of the ship but according to no definite law; hence an example should be worked up to give a reliable comparison.

Table II shows the above expenses arranged as percent-

ages of the annual operating expenses. This table shows clearly the importance of the various annual expenses.

Capital charges, which are fixed by the first cost of the ship and the cost of repairs and overhauling, is the largest item, being about $\frac{1}{3}$ of the total expense of operation.

Stevedoring of the cargo is the next largest item and averages about $\frac{1}{5}$ of the annual outlay for operation.

TABLE II.—OPERATING EXPENSES ARRANGED AS PERCENTAGES

	1	2	3	4
1. Capital charges	33.0	36.7	26.5	37.6
2. Fuel, lubricating oil and water.....	16.6	15.2	13.4	18.8
3. Brokerage and management	8.6	7.1	6.9	9.8
4. Crew and subsistence	10.0	11.3	8.1	11.5
5. Port charges	7.6	9.7	6.1	8.6
6. Stevedoring	24.2	20.0	39.0	13.7
Total operating expenses	100	100	100	100

Observations made by the writer lead him to believe that present day methods of cargo handling can be greatly improved upon. The most important factor of course is labor and at present the shipowner is more or less at the mercy of the stevedores. Yet, if the union stevedore can handle sugar at the rate of 70 tons per hatch per hour at 40 cents per ton, why should a shipowner pay \$1.50 per ton for general cargo and tolerate a speed of 18 tons per hatch per hour?

The size of the draft today averages about $\frac{1}{2}$ ton which is about the best that can be handled without becoming too bulky and unwieldy. The number of drafts per minute, however, is very low, averaging in most cases between $1\frac{1}{2}$ to 2 minutes per draft. If a rate of 1 draft per minute could be maintained, the 30 ton rate per hatch would be possible and with $1\frac{1}{3}$ drafts per minute 40 tons per hatch could be maintained.

METHODS OF HANDLING CARGO

The following systems and methods of handling cargo are in use today:

- (1) Swinging boom (one boom, one winchman, one hook).
- (2) Burtoning by yardarm method (2 booms, 1 or 2 winchmen, one hook).
- (3) Burtoning with 2 hooks (2 booms, 2 winchmen, 2 hooks).
- (4) Pier crane in combination with one ship boom.
- (5) Conveyors.
- (6) Conveyors in combination with any of the above.

Any of the above systems may be used in combination with the skid, if the marginal way between the ship and the pier shed is too narrow. For any of the systems to work efficiently, however, there should be a marginal way about 35 feet wide between the ship and the transit shed. The necessity for this will be clearly shown later on.

(1) The swinging boom, although still used to a considerable extent, is far too slow and antiquated to receive any consideration.

(2) In the burtoning system, where only one hook is used, one boom is stayed over the hatch and another over the ship's side. The draft of cargo makes a continuous movement from ship to pier. Generally two men are employed to operate the winches, one slacking off while the other hoists. Frequently one man can manipulate both winches, thereby saving the cost of one man. In the hands of skillful stevedores and with proper equipment, good speed can be maintained with this system.

BURTONING WITH TWO HOISTS OFFERS BEST POSSIBILITIES

(3) The method of burtoning by the use of two hoists, however, offers the best possibilities for speed and efficiency. In this system one boom and hoist handles the cargo from the hold to the deck and the second from the deck to the pier or vice versa.

Today, the method of operating this latter system is often

very inefficient. In unloading, the draft from the hold is frequently not placed on deck until the one previously placed there has been removed and the draft to the pier is held suspended until stevedores arrive to take it. Used in this way the system is very slow and the real advantages of it are lost.

Properly used the system should have two reservoir piles, one on deck and one on the pier so that delays at one hook will not cause a delay all along the line. Thus, if each hoist works independently of the other, several drafts will be accumulated on deck and several on the pier. With this arrangement any accident or delay at the hatch boom will not cause a delay at the wharf boom or among the stevedores on the pier. The accumulated drafts on deck will act as a reservoir supply for the wharf boom until the hatch boom is again in operation. Similarly, if an accident stops the wharf boom, the stevedores have a reservoir pile on the pier to draw from. By the use of this reservoir principle a continuous stream of cargo can be maintained from ship to pier or from pier to ship and, with a sufficient number of stevedores, between 30 and 40 tons per hatch can be maintained.

Ordinarily this system is much faster than the yardarm system, which uses one hook, because the reservoir principle is lacking with the latter. However, when uniform cargo carriers are used which can be placed directly on electric or trailer trucks and when there are plenty of trucks and carriers available so that there is absolutely no waiting for a draft in the hold or on the pier, the speed of this system can often be made equal to, if not better than, the two hook system.

(4) The pier crane while capable of handling heavy drafts is at a disadvantage because of its speed. Ordinarily

a draft of much over a ton becomes too bulky to handle; so a crane of large capacity is of no advantage for general cargo. If used in conjunction with one ship's hook, the pier crane can handle two drafts at one swing. It is of particular advantage when handling cargo to or from an upper deck of a pier. However, the pier crane offers no advantage over ship's booms and except for two deck transit sheds or for special heavy pieces is not to be recommended.

Conveyors have not been used to much extent in handling cargoes to or from ships. For standard package cargo there is no reason why conveyors from ship to pier and conveyor hoists from hold to deck should not show better speed and labor costs much below any of the other systems.

WIDE MARGINAL WAY SHOULD BE PROVIDED

No matter which system is used a marginal way about 33 feet wide should be allowed between the ship and the transit shed. This allows plenty of space for the pier reservoir and results in much saving of time both in receiving and discharging cargo. Comparatively few American piers have this marginal way and hence the skid must be used which causes untold delay and confusion on the pier.

In stowing cargo the draft should be unfastened from the hook as soon as it has been placed in the hold. Frequently long delays take place in the hold because the hold gang attempt to stow each draft while it is still fast to the hoist. The hold gang and the pier gang should be of sufficient size to keep pace with the ship's tackle.

Although the foregoing discussion is based on theoretical ships, ideal trade conditions and certain assumed data, it shows clearly the gains in profits that may be expected by a reduction in stevedoring rates and quicker turn-arounds.

Steamship America Saves 1,400 Tons of Coal in Three Voyages

LAST fall, considerable comment was made in marine circles regarding the performance of the S.S. *America*, operated by the United States Lines for the United States Shipping Board.

This vessel had been selected by the Fuel Conservation Committee, which is composed of Captain C. A. McAllister, Commander R. D. Gatewood, Colonel George Bartlett, Major George M. Talbot, Maurice Healey, E. A. Peabody, D. M. Myers, H. B. Taylor, F. B. Webster, C. J. Jefferson, E. A. Stevens, C. H. Jack, as an example of what could be done to increase the efficiency of operation of some of the vessels of the American merchant marine. The port staff of the United States Lines and the engineer personnel of the vessel co-operated heartily in the program.

The results of the first voyage were made public and showed remarkable saving. However, there was considerable skepticism as to whether or not this saving would continue. On December 9, the *America* completed her third voyage since the furnace fittings had been modified and the total fuel savings for the three voyages now totals 1,400 tons, the vessel operating with the same speed and draft conditions as she had previous to the changes.

Fig. 1.—Former Arrangement of Grates and Bridge Walls as Installed by the Germans

Fig. 1 shows the condition of the furnaces as they were previous to the changes. This is a typical installation used on all the double-ended boilers of the ex-German ships by the Germans. It will be noted that the combustion chamber has practically 30 percent of its volume cut out by the brick division wall and the long sloping brick bridge wall. The grate surface in this case was 6 feet 3 inches long and it was practically impossible for the firemen to work the rear end of the fires.

Fig. 2 shows the furnaces as they now are. The combustion chamber has been cleared of all brick work and now affords a reasonable volume in which the gases can complete their combustion. The grate bars have been shortened 9 inches so that the entire fire can be worked.

The cumbersome long sloping brick bridge walls have been replaced with a cast iron ventilated type of bridge wall which permits sufficient air to enter the rear end of the fire to complete combustion and to eliminate the troubles arising from large clinkers growing at the bridge wall.

By carrying out the principles of good fire room practice, that is, keeping the ash pits cleaned out and the opening between grate bars and between the sections of the bridge wall free of slag or ash, the operating personnel has kept this equipment in its original condition and no maintenance charges have been necessary up to date.

Fig. 2.—Improved Arrangement of Grates and Bridge Walls Made By Shipping Board Fuel Conservation Committee

Curious Incidents in the Careers of Hoodoo Ships

Of All Superstitions the Commonest and Best Justified Is the Belief That Some Ships Are Accursed

By Robert E. Annin

THE moving incidents of deep sea experience will always have an interest and charm, even for those whose daily occupation would tend to make them commonplace. It was by his fetching narratives that Othello induced Desdemona to waive the color line and the financial uncertainties of seaborne security are the theme of parts of the "Merchant of Venice." Certainly, unless a man is almost devoid of nerves, the anxieties of a fleet are likely to give him many nights of broken slumbers, and a feeling of trepidation as he opens the morning radiograms. From the constant strain always inherent in the business, have arisen the superstitions for which sailors as a class have been notorious, and from whom they have spread to the shore workers and offices.

In old times, for example, an owner would not sail his ship on Friday, if it could be avoided; and the average sailor would not sign on a ship booked to sail on the sixth day of the week.

But with the absolute necessity of quick turnaround on large and expensive ships the "Friday superstition" has long been falling into disuse, and steamers sail as soon as ready, wasting neither time nor money on unreasonable prejudices. The result of this has been the exploding of this particular notion, despite the "guaranteed" story of the English owner who had his ship's keel laid, ship launched, and sailed on Friday. She was named the *Friday* and was intended to break up the "Friday" idea, but she was never heard of after leaving port on her maiden voyage.

Of the superstitions which remain, the commonest, and probably the best justified, is the belief that some ships are accursed (as it used to be phrased) or, in modern vernacular, "hoodooed." Any underwriter of experience will admit that there are ships on which he will not accept any portion of the risk, although they may meet all required conditions as to construction, equipment, supply and personnel. But careful insurers refuse them simply on their record. It is impossible to say what makes a ship "unlucky," but there are vessels which no experience, foresight, care or expense seem to be able to keep out of trouble. Such ships are a sorrow to owners, a terror to operators and a thorn in the side of underwriters.

The "hoodoo" ship meets only the chances and incurs only the perils which threaten her more fortunate sisters—Acts of God, negligence, incapacity and dishonesty. But what really marks her as a "hoodoo" is that one or the other of these roots of bitterness is at work on her all the time. Hence neither ship nor owners ever get a fair chance to "rest up," physically or financially. Any ship is liable to have an occasional incompetent in command; but the hoodoo ship always has him on the hard voyage and in the emergency. Any ship may have dishonest agents and officers; the hoodoo ship has them both at the same time, working together in a distant port, where the owner will never know what is going on until too late. Ordinary ships have their hard luck spots, and get over them. The "hoodoo" distributes her misfortune economically, so as to have at least one in reserve for each new voyage.

One final peculiarity of the real hoodoo is that she never becomes a total loss. She may be stranded, sunk, burned or in collision, but there is always too much of her left to abandon. Thus she is repeatedly repaired, at an expense which fresh misfortune is likely to render useless, until age, the Act

of God or the disgust of owners put her out of business. Her cargoes may be damaged, her officers wiped out, her crew swept away by pestilence, but the ship always turns up ready and anxious for more repairs. She repeatedly meets conditions which would destroy any ordinary vessel of her class; but whoever may be hurt or killed, she is always saved to gladden the heart of the drydock. Hence the time which the ordinary vessel uses to earn expenses and income is put in by the hoodoo in trying to pay for dead horses.

THE ST. PAUL

An example of the bad combinations that strike unlucky ships may be found in the sinking of the steamer *St. Paul* in New York harbor on April 25, 1918. The vessel had been drydocked in Brooklyn and was being towed to her North River pier when she listed heavily, turned on her side and sank. Investigation showed that an ash port on her port side had been left open. This would have done no harm had her ballast been well distributed, nor even then had the ship remained on a fairly even keel during her short tow from dock to pier. But there was a good deal of wind and a swift spring tide. As the ship, rather cranky at best, met the wind and turned to cross the tide, she listed so as to put her ash port under, and the foundering followed in due course. It takes a pretty unlucky ship to have a spring tide, a head wind, and badly trimmed ballast combine with a careless seaman to sink her. And it should be remembered that had the seaman left open a port on the starboard side no harm would have ensued.

The *St. Paul*, however, had quite a record of misfortune for a passenger ship of her class. After sticking on the ways at her launching she had a rather hectic career, but the chief incidents were her sinking of the British warship *Gladiator* in 1908 and sinking herself in 1918.

A sample voyage of another unlucky steamer probably established a record in the matter of towages and ports of refuge on a transatlantic trip. She carried coal from Charleston, S. C., to Nantes in 1921. She put in at the Azores, was picked up helpless in the Bay of Biscay and towed to point St. Mathieu. Thence she proceeded to Brest for repairs and proceeded up the river for Nantes and grounded; was pulled off and towed to Nantes, repaired and sailed for home. She made port at Brest for repairs; put in at Azores for water; sailed thence for New York; was picked up 1,000 miles east of Sandy Hook and towed to Scotland light, where she was left to proceed under her own steam to quarantine. She made Gravesend Bay as her last port of refuge, anchored and whistled for a towboat. Instead of the fifty days estimated for the round trip, this ship took four months. The profits may be easily imagined. But this was not all "hoodoo." She had just undergone extensive and expensive repairs under Government supervision, and had been inspected and certified as ready for sea in hull, engines and equipment. One would like to ask who "certified" her and what he got for it.

A REAL HARD-LUCK SHIP

For the case of a genuine "Jonah" ship a part of the record of a large American schooner almost transcends belief. It should be stated for reasons obvious to those familiar with wartime construction that she was well built some years be-

fore the war, by an excellent builder, and there was no apparent reason why she should not do at least as well as the average of her type.

In the spring of 1917 this vessel arrived at Port Natal with a cargo of lumber from "The States." She loaded a cargo for New York and sailed. Two days out, she was struck by a hurricane, suffering some damage and losing many of her sails. It was deemed wise to return to Port Natal and repair damages. She did so and a week later sailed again. Three hundred miles out she was struck by a gale, lost many sails and her anchor chains came down on her sea cock, breaking it and threatening to flood the hold. Pumps were set to work and a steamer hailed, which put out a line and started to tow. After breaking three tow lines the steamer resigned the contract and the schooner limped into port under canvas. Survey was held with the result that the ship was ordered discharged and docked; sails were ordered by cable, to come per steamer from New York. This was in mid-July, 1917. At this stage the master decided that he had had enough and resigned, turning over the command to the chief mate. The ship waited her turn at drydock until mid-September, when work was started. It was November before she was reladen and ready for sea.

The next that was heard of her she had taken refuge within the Delaware Capes, loaded with ice, running rigging frozen and crew ready to mutiny. This was early February, 1918, so that, evidently, in addition to being no Mascotte, she was no ocean greyhound. She was towed up the coast to New York and, since the topmasts were not struck before passing up the East River, she hit the Brooklyn Bridge and carried them away. She discharged a pretty good cargo (considering) and was sent to drydock for \$15,000 worth of repairs (March, 1918). She waited six weeks for her turn at the dock; the repairs lasted until late July and cost \$60,000.

In August, 1918, she loaded for Buenos Aires. Sailing for that port she collided with her towboat in Ambrose channel, breaking four planks, and returned for four days' repairs. Again she encountered a cyclone in the Caribbean, lost her deckload, sustained heavy damages and limped into Buenos Aires in December a partial wreck. At Buenos Aires she discharged and refitted. Cargo was damaged, and the seeds of several suits planted. The expense bill was about \$40,000. She then took on a cargo of wheat for the Mediterranean and sailed; off Rio Janeiro she was found to be leaking and as the pumps were choked with wheat she put in Rio as port of refuge, making four general averages and four ports of refuge in twenty months. She sailed in April, 1919, for the Mediterranean, and in July put into the Azores, short of provisions, water and money. Finally she arrived at her discharging port in early September, having taken a year for the voyage from New York via Buenos Aires. While discharging she caught fire, but was not much damaged.

To follow in detail the history of this ship would only create incredulity. Her actual record of disaster transcends any hard luck story of Kipling or Jacobs or Clark Russell. The main incidents of the next two years are therefore merely summarized.

In September, 1920, she was partially destroyed by fire while in drydock. In October of the same year she went ashore on the Atlantic coast twice within forty-eight hours. In December she grounded in a southern port and, proceeding to sea, developed such openings of her seams that her pumps could not clear her. She was towed up a southern river and anchored over a (supposed) mud flat. When the tide went out she was found aground on an uncharted sunken rock, which almost broke her in two. In 1921 she encountered a cyclone and was towed into an Atlantic port, drydocked and fell off the blocks as the water receded. Early in 1922 she sailed from New York for the south Atlantic coast of the United States, but put back three weeks later and struck on an unknown rock in Newtown Creek.

It may be added that this schooner was launched on a Friday and stuck on the ways in launching. (This the writer understands to be a fact and not a bit of belated jocosity.)

An analysis of the three years of disaster (so far as details are available) would show that of the vessel's misfortunes about 20 percent were due to misjudgment or negligence; 30 percent to "Acts of God"; and the remaining 50 percent to an unfortunate conjunction of circumstances, aided by the causes above named, singly or together.

Now comes an oddity in the history of this floating sorrow. For over three years she had had an uninterrupted record of calamity, under good and bad agents and officers, which one may be sure were often changed. There was no question that her owners and managers had done all that care and money could do to make the ship successful. The only result had been the record above sketched, and a rising rate of insurance premiums.

The time now arrived when she could not be insured at all. The owners therefore had to choose between running her uninsured or letting her rot at anchor. They chose the former *and since then have had no trouble with the ship.*

A more cheerful and yet rather surprising incident marked the voyage of the American iron ship *Brynhilda* from New York to Port Elizabeth, South Africa, in September, 1918, when our coast was haunted by hostile submarines and all traffic was under rigid rules and secret official orders. Moreover, the harbor lights were doused or changed; all ships were sailed with lifeboats provisioned and swung outward, and all use of the radio was forbidden except in last extremity. These secret orders as well as routing were given to the master only when he was on the way to his ship.

The *Brynhilda* sailed one Saturday in late September, just about dusk. Two days later one of her lifeboats was picked up off Long Beach, badly stove in and otherwise damaged, and in a condition which aroused grave fears for the ship. As she had a wireless installation, the coast was at once swept with tracing messages, but without result. All likely ports were watched for news from incoming ships, but there were none that had seen or heard of the missing vessel. As time went on and she was due to be in wireless range of the west coast of Africa, endeavors were made to trace her from there, but there was absolute silence. The friends of the officers were in despair, the owners were gloomy and the original underwriters re-insured freely, paying as high as 60 percent premium. The ship was due about Christmas, but the conviction of her loss was so strong that no one expected to hear of her. It was supposed that her bones lay within one hundred miles of the Narrows.

On Christmas morning the *New York Herald* had this simple item in the Shipping News: "*Port Elizabeth, Dec. 21st. Arr. Am. Ship Brynhilda, New York.*"

One man in New York spent a large portion of his Christmas in getting hold of the families of the officers of the ship and repeating the *Herald* despatch as Christmas cheer. It was the most worth-while Christmas he ever spent—a real Christmas denouement.

What had happened was this. As soon as the tug had cast off, the ship broke out her sails and laid her course for the lightship. In the dark she was side swiped by the iron standard of a high channel buoy, carrying away a port lifeboat and part of the davits. The master would have turned back, but that would have meant two days loss of time, which was more than the boat was worth. He could not radio the accident, owing to the Navy instructions to use the wireless only in extremity. Under these circumstances, he decided to proceed, not doubting that the wrecked boat would sink with the weight of the davits and supplies. None of the tracer messages ever reached him; he had a prosperous voyage and was amazed to learn on arrival that his ship and crew had been given up for lost.

Deadweight

By Edwin C. Bennett*

Notwithstanding the fact the deadweight carrying capacity of a ship is the factor of greatest importance to shipowners, operators, charterers and those "who go down to the sea in ships," it is noticeable that while the meaning of the term deadweight is known in a general and superficial way, a true understanding of all that the term includes is known to but a comparative few of the shipping fraternity. This lack of a full and complete understanding of what deadweight actually includes is responsible for innumerable altercations and many lawsuits between sellers and buyers, owners and charterers and others engaged in marine transportation. To aid in clearing up such misunderstandings the following explanation is offered.

IF we exclude passenger liners and certain special ships we can safely assume that deadweight is the basic income earning factor of every commercial freight carrying vessel,—it is the one income earning factor into which all expenses incurred in operating the vessel must be resolved. It is the one factor of the vessel that is marketed and upon the success or non-success of that marketing depends whether the vessel earns a profit or incurs a loss.

Deadweight, as considered in a broad and all embracing explanation of the term, is the difference between the light weight of a vessel and the displacement at any specific draft. For instance, a vessel whose light ship weight is 3,380 tons and whose displacement at 23 feet draft is 11,300 tons has a deadweight at that draft of 7,920 tons. This deadweight, however, does not represent the weight of paying or income earning cargo the vessel can carry, for many items necessary for the operation of the vessel are included therein.

LIGHT SHIP WEIGHT

In order therefore properly to appreciate what deadweight is we must first know what is meant by light ship weight. Light ship weight is the total weight of the completed ship including its machinery with steam up and water in the boilers up to steaming level, water in the condensers, pumps, feed heater, permanent equipment such as tow lines, anchors, chains, etc., life and working boats, standing and running rigging, flags, awnings, navigating and engineering outfits and spare parts, mess, cabin and culinary outfits necessary to make the ship navigable and habitable. It does *not*, however, include coal or oil fuel either for boilers or galley use, consumable stores whether for engine, deck, cabin or galley use, drinking water, boiler feed and sanitary water, dunnage, ballast, both solid or liquid, crew and officers and their personal effects. The above excluded items are all part of the deadweight and therefore their combined weights must be deducted from the gross deadweight of the vessel at any specific draft in order to determine the actual weight of paying or income producing cargo that can be carried or marketed at that draft.

It will be seen therefore from the foregoing that when a vessel is ready to make a sea voyage a certain amount of its deadweight carrying capacity is used up even before a pound of cargo is taken on board. The amount thus taken depends, of course, upon the length of the voyage between ports for it stands to reason that a vessel whose length of voyage between ports is but 500 miles will require less fuel, water and consumable stores than a vessel whose length of voyage between ports is 2,000 miles.

DENSITY OF THE WATER MUST BE TAKEN INTO ACCOUNT

When it comes to a question of determining both the light ship weight and the gross deadweight of a vessel from her

draft figures forward and aft, the factor of the density of water must also be taken into account. It is fundamental that the weight of any floating object, such as a ship, is equal to the weight of water displaced, and, keeping in mind that at 62 degrees F. fresh water weighs approximately 62.4 pounds per cubic foot and salt water weighs 64 pounds per cubic foot, it follows that a ship floating in fresh water displaces a greater volume of water than if floating in salt water; or, in other words, the draft of water of the light ship is less in salt water than in fresh water. While there is also a difference in weight of water dependent upon its temperature—water at 85 degrees F. temperature being about $\frac{1}{4}$ pound lighter than at 35 degrees such refinement is very seldom taken into account in the general consideration of deadweight. As a matter of interest, however, in a 9,000-ton deadweight ship the difference in deadweight between sea water at 35 degrees and 85 degrees is about 50 tons at her load draft.

The great majority of shipowners, charterers, etc., in determining the deadweight capacity of a vessel for any specific draft refer to and read it from the deadweight scale or table supplied by the shipbuilder. As a matter of fact, it is the only information in their possession from which such information can be obtained, and, such being the case, it is imperative that it be correct and reliable.

Unfortunately, so many conditions are reflected in the computation of the deadweight scale, especially in the case of old vessels, that it is safe in saying a large proportion of the deadweight scales now in use on shipboard do not reflect the true deadweight that the vessel carries.

INACCURACIES IN DEADWEIGHT SCALE

In explanation of this assertion, it should be remembered that the deadweight scale or table is prepared by the shipbuilder's technical staff under conditions generally favorable to the vessel. Furthermore, while the shipbuilder appreciates the importance of an accurate deadweight scale, it is a matter of professional pride to show the greatest amount of deadweight for any specific draft.

At the time the shipbuilder determines the deadweight, the vessel has but few coats of paint, her ballast tanks are absolutely dry, the bottom of ship is clean, as are also the cargo holds, fuel bunkers, etc. After a vessel goes into commission, she acquires additional coats of paint, the water ballast, reserve feed water and other tanks, even when supposed to be pumped dry, contain a certain amount of water or oil, additions and changes are made to vessel, additional quarters are added, new floor covering is laid down, engine room spare parts or equipment are added—the vessel is converted to fuel oil burning while retaining her coal burning fittings, etc., all of which are accumulative and in the aggregate amount to a weight that has an appreciable bearing upon the amount of paying cargo that can be carried.

In the foregoing, the draft figures at the stem and stern of the vessel have been considered as being correctly located

*Naval architect-engineer, marine surveyor and appraiser, 15 Broad street, New York.

with reference to the under side of the vessel's keel, or in the case of a flat keel plate, from the underside of the keel outer buttstraps. A number of cases have occurred within the experience of the writer where the draft figures have been incorrectly located on the ship and therefore the amount of deadweight the vessel carried on any specific draft was incorrect in relation to the actual draft of the ship; or, if taken in relation to freeboard marking, it is generally less than what the vessel can actually carry.

It is desirable, therefore, that shipowners, especially in the case of old ships, or those known to have had extensive additions or alterations made thereon, have the deadweight scale or table checked up to assure themselves of its accuracy. Such a check should always be demanded by the prospective purchaser of an old ship in order to be assured that the deadweight as stated by the seller or as shown on the vessel's deadweight capacity tables is reasonably accurate and has taken account of the increased light ship weight that comes with years of service.

DEADWEIGHT CARRYING VS. PAYING CARGO CAPACITY

In order to illustrate more clearly the relationship between the deadweight carrying capacity and the paying cargo carrying capacity, there is given below the weights for a cargo carrying vessel of the usual type reputed to be of 7,800 tons deadweight, but which actually carried, at the time she was built, 7,868 tons at her legal summer freeboard draft—the vessel being outfitted for a voyage of 3,600 miles.

WEIGHTS FOR CARGO VESSEL OF 7,800 TONS DEADWEIGHT

	Light Ship, Tons	Deadweight, Tons
Weight of dry ship at time of her completion by shipbuilder	3,268	
Water in boilers, condensers, pumps, etc.	82	
Additions to structure and equipment added after vessel left shipyard	30	
Actual present light ship weight	3,380	
Coal for 3,600 miles plus reserve.....		700
Reserve feed water for boilers		120
Drinking water		20
Sanitary water		5
Galley stores, galley coal, etc.		15
Deck and steward's stores		25
Engine room stores		5
Crew and effects		6
Water in ballast tanks that cannot be removed by pump suctions		10
Dunnage for cargo		2
Non-income producing deadweight		908
Weight of income producing or paying cargo		6,960
Total gross deadweight		7,868

Inasmuch as the tons per inch at load draft were approximately 44, it will be seen that about 20 inches of the vessel's draft was taken up by non-income producing deadweight, or putting it in another way, about 11½ percent of the gross deadweight is required for non-income paying items. Of this 11½ percent some 90 percent is in turn taken up by the combined weights of coal and reserve feed water.

While it has but an indirect bearing upon the foregoing explanation of deadweight an analysis of the above table will show that in order to increase the weight of paying or income producing cargo that can be carried, it is necessary to reduce either the weight of the light ship or the fuel and boiler feed water or both. Any type of machinery that will reduce the consumption of fuel and feed water will obviously increase the weight of income producing cargo that can be carried and is therefore a subject that should be seriously investigated by all shipowners.

Resolute's Stern Frame Successfully Welded

ON November 17 an inspection of the transatlantic liner *Resolute* of the United American Lines, which was in dry dock at the Morse Dry Dock & Repair Company, Brooklyn, N. Y., revealed the presence of a fracture directly through a splice half way out on the 10 inch by 15 inch stern shoe.

To have replaced the old 16-ton casting by a new one would have cost many thousands of dollars and involved unshipping the old section, purchasing a new casting and installing and machining a new splice. This course of procedure would also have delayed work on other alterations to the vessel while in dry dock, preparatory to sending the ship

Repairing Stern Shoe of S. S. Resolute. Thermit Welds With Collar on Side Chipped Off to Allow Replacement of Plates

on a cruise around the world, which could not be attempted until the stern shoe was repaired.

It was found entirely feasible, however, to save much time and money by means of Thermit welding. Instead of making a weld through the broken splice, it was recommended that a more satisfactory job could be obtained by cutting out the splice and welding in a new billet by making two welds, thereby entirely eliminating any mechanical connection and obtaining one solid section of much greater than the original strength. The method of welding suggested was approved by the dry dock company, which in turn obtained the approval of German Lloyds, under whose registry the *Resolute* was classified.

Permission to weld being granted, the dry dock representatives lost no time in removing adjacent plates, cutting out the old splice and forging, machining and inserting a new billet, 4 feet in length, in place ready for the welding force to proceed. Work began at 9 A. M. Sunday, November 19, at which time the wax patterns were applied. By 5 P. M. the mold boxes were in place and had been rammed. Pre-heating was then started, using one heating gate on each side of each weld. Pre-heating was continued steadily until midnight, when the charges of Thermit in the crucibles, suspended by chains over the mold, one crucible on each side for each weld, were ignited and the welds poured simultaneously.

The welds were allowed to cool over night and the following day the mold was stripped off and risers and pouring gate removed. The collars of the welds were chipped off on the sides, in order to allow replacement of plates. The weld on inspection was found to be perfect in every respect and additional repairs were started under way promptly.

Recent Developments in Marine Insurance

Review of 1922—High Repair Costs—Turkish Monopoly—
New P. and I. Bureau—Unseaworthiness—Danube Scheme

By "Bordereaux"

OF the year so recently ended it may be said to have been, so far as marine insurance is concerned, one of encouragement and advance. The reaction from the disastrous experiences of 1921 was marked, and the year closed with an improvement in premium volume, reduction of losses and general betterment of conditions. It was a distinct period of reconstruction. It opened under circumstances of discouragement, because many companies were failing and retiring, both here and abroad, and because losses were coming in steadily for three years' accounts. Foreign trade was almost dormant; there was practically nothing to write. Then things began to look up. The flow of losses abated, particularly as regards theft and pilferage, shipments of cotton and grain to Europe aroused something of the old animation in the market, and trade began to quicken from Cuba and South America. Thus, when 1922 passed out it left the marine underwriters with quite as much of an income as they had had the previous year, and considerably less money to have to pay for losses. It's encouraging.

Ship Repair Costs High

AN interesting graph has been prepared by the United States Salvage Association which reflects a comparative study of ship repair costs in the New York District covering the period from 1913 to and including 1922.

Data Compiled by United States Salvage Association Showing
Cost of Ship Repairs in New York District

The average cost curve is influenced chiefly by three factors: Labor rates, drydockage and the price of steel. These are the dominating influences, although there are other minor factors such as freight rates, overhead and handling charges, etc. This graphic picture shows that the cost of effecting repairs at the present time is about 100 percent greater than in pre-war days.

Dividing the total cost into its component parts, it is of

interest to trace the rises and falls in the cost of individual items. Take ship mechanics' wages, for example. Starting with an average wage of \$4.50 in 1914 and 1915, the scale rose rapidly until, for the two years subsequent to the armistice, it rested at \$10.96 per diem. It has declined somewhat since, but still stands at the high figure of \$8.96. Prices for steel plates at the mill present a no less significant history. As soon as the late war broke out they began to ascend from \$1 per hundred pounds until they reached \$4.50 a hundred shortly after the United States entered the conflict. The decline, when it came, was equally precipitant, reaching the \$3.30 level in the late fall of 1917. Early in 1922 it got down to \$1.30, when it started upward once more and is now in the neighborhood of \$2. Dry-dockage costs, on the per gross ton basis, rose to 16 and 14 cents from between 1918 until the close of 1921, but has since declined to 5 cents, which is practically the rate charged in 1914 and materially less than that of 1913.

Turkish Monopoly Proposed

TURKEY is accumulating confidence at such a rate that it plans making a monopoly of all kinds of insurance.

If its tentative arrangements go through it will expel all foreign insurance interests and found a bank to carry on the business. This might, at first blush, look bad for foreign merchants doing business in Turkey, but there will doubtless survive the principle of extra-territoriality—for that is something the European Governments will never relinquish—and the result will doubtless be that English and American shippers, for example, will insist upon coverage in companies whose strength they are acquainted with and will let the foreign-hating Turkish bank severely alone.

Government P. and I. Bureau

AS is generally understood, there are numerous liability hazards that are not covered by the ordinary marine insurance policy—such as personal injury, sickness, cargo damage, immigration fines, etc. These have heretofore been separately written by the American Steamship Owners' Protective and Indemnity Association, and Shipping Board vessels have been covered in that way. But it has been decided by the latter to withdraw the Emergency Fleet Corporation from this Association on February 20 and to insure its P. and I. liability in a new organization of its own launching, which is to be known as the United States Protective and Indemnity Agency, Inc. It is to be located in the Shipping Board offices in New York City, and Nathan A. Smyth, general counsel for the Shipping Board, has been selected to be its president. It will begin to operate on February 20.

The idea is to give this body a world-wide scope and representatives are being appointed in all the principal ports of the world. Close cooperation is to be had with managing agents and they will be given considerably more latitude as respects claim settlements. There is to be no separate insurance fund established, but current receipts will be used to meet claims. The field of the new bureau will be one of adjusting and investigation.

Relative to the past P. and I. experiences of the Shipping

Board, Commissioner Lissner has recently given out the following data:

The Shipping Board paid into the Steamship Owners' Association last year about \$5,000,000 in premiums, but later reduced this expense about \$2,000,000 by withdrawing insurance for its idle fleet.

Under the new arrangements the Emergency Fleet Corporation will carry its own insurance, just as is already done with regard to all other Government insurance risks. Losses will be paid out of funds appropriated by Congress for maintenance of the Emergency Fleet Corporation as a shipbuilding concern. The United States P. & I. Agency will serve only as a loss adjustment agency.

The former Shipping Board believed it advantageous to enter into the American Steamship Owners' Protective & Indemnity Association in order to build up this form of mutual marine insurance organization in America, whereas formerly all such organizations had been under British control. And, moreover, at that time the Shipping Board had its hands full with a construction program and the organization chaos growing out of the war pressure.

But now the American Steamship Owners' Association has expanded until it has entered on its books more than two million gross tons of privately owned shipping besides that belonging to the Shipping Board. And, also, the Shipping Board has built up an organization within itself capable of handling much of the work that has been handled by the American Steamship Owners' Association. The new arrangement will do away with most of this duplication of effort.

The withdrawal of the Shipping Board from the American Steamship Owners' Protective & Indemnity Association opens up a number of technical questions relating to the liability of the Shipping Board in connection with past transactions with the American Steamship Owners' Association. The Shipping Board believes itself entitled to large refunds on business handled by the association in the past. It is the intention of the Shipping Board to press these claims against the association so that in the final settlement an equitable adjustment may be made.

Average for Stiffening

CHARTERERS may maintain a claim to general average contribution against the owners of a vessel in such an instance as when it is necessary to remove coal that was taken aboard for stiffening and which subsequently became heated and imperiled the ship prior to loading. This was decided in a case recently tried before the United States Circuit Court of Appeals, *Aktieselskabet Fido v. Lloyd Brasileiro et al.*, 283 Fed. Rep. 62. The court held that all losses in a maritime adventure falling outside the contractual obligations of the parties, and which arise from a voluntary sacrifice of a part of the cargo, made to save the whole adventure from perishing, or which arise out of extraordinary expenses or expenditures of money incurred for the joint benefit of both ship and cargo, constitute a claim to general average contribution.

The circumstances of this case were unusual. Seven steel sailing vessels were involved, all the property of the Norwegian company, under charter by the respondents to carry full cargoes of coal from Hampton Roads, Va., to South American ports. The charter parties carried the anomalous provision that the charterer should furnish ballast, or a part cargo of coal, as stiffening, to enable the vessels to proceed from their inward ports of discharge under previous charters. Bituminous steam coal was taken on for this purpose at New York and Baltimore to make the run to Hampton Roads for the full cargoes. While the ships were waiting their turn at the loading pier of the latter place it was discovered that the coal stiffening had become so heated as to make it unsafe to load the balance of the coal full cargoes; and the stiffening was accordingly removed and entire new cargoes loaded, after which the vessels proceeded to their respective destinations in South America. It was agreed on both sides that the removal of the stiffening coal was necessary, but because of the delay and expense involved a difference of opinion arose between owners and charterers as to the rights and liabilities of the respective parties. One of the questions was as to when lay days began to run; this was decided by the court to be after the removal of the heated stiffening.

Amendments to Repairs Tariff

SHORTLY before the close of the year amendments to customs regulations were promulgated by Assistant Secretary of the Treasury Clifford, but they fail to help the underwriters out of their dilemma on the subject of repairs duty refunds. The Clifford amendments are intended to give the necessary procedure in case of making entries in connection with repairs made abroad subject to duty under the new tariff. They do not clear up any of the ambiguities of the new Act that are proving so puzzling. In a word, the amendments are of method only, prescribing procedure, and further Treasury rulings must be forthcoming, if vessel owners and marine underwriters are to know just where they stand in respect to such points as we pointed out in this department in our January issue.

Unseaworthiness

THE burden of proof on the issue of unseaworthiness in a suit on a marine policy rests with the insurer, and under the "Sue and Labor" clause the insurer is not liable for contribution to the expenses incurred. These are among the interesting points held by the United States Circuit Court of Appeals, Third Circuit, New York, in the suit brought by the Liberty Sand & Gravel Company, Inc., against the American Merchant Marine Insurance Company, 282 Fed. Rep. 514.

Liability on the Danube

HITHERTO it has been customary on the Danube for shipping companies to either totally exclude any liability for goods taken over by them, or to restrict it to such small sums that the shippers have been obliged to insure the goods themselves. But now the associated Danube shipping companies have decided to assume liability for loss, damage and non-delivery and all risks to cargo (excluding acts of God, peculiar nature of the goods, personal negligence of the despatcher or consignee, etc.). To this end, in addition to the freight and other charges, they are levying on the goods a special supplementary liability charge and, in consideration of this, will pay to the shipper the full market value of the goods on the day and place when and whence they are taken, and possibly also an additional sum of 15 percent of this value as compensation for lost profit. The shipping companies have also made arrangements that goods destined for transport on the Danube can be, or are, covered for the preliminary or subsequent railway transport, in so far as the receiving railway station and the preliminary and subsequent railway transport and the railway station at the point of destination lie within the territory of the Danube States, and so long as the preliminary and subsequent railway transport is not used as a means of avoiding transport by water. Special supplementary charges are to be levied for the handling of goods during the winter.

Company Merger

THE Washington Marine Insurance Company, which was organized in 1918 and has chiefly done a marine business, has been merged with the United States Lloyds of 1 South William street, New York. The assets and outstanding business of the former were taken over as of January 1, 1923, and the New York Insurance Department has given the merger its official sanction. Thus passes still another of the "war babies" that were attracted to marine insurance by the glittering prospects of war risk business but could not find a reason for existence when there was nothing in sight but straight marine insurance.

S. S. City of Nagpur; (1) First Class Smoking Room, (2) First Class Lounge, (3) Veranda Cafe, (4) Main Engine

Passenger and Cargo Steamship City of Nagpur

Recently Completed by Workman, Clark and Company, Ltd.,
Belfast, Ireland, for City Line Fleet of the Ellerman Lines, Ltd.

THE *City of Nagpur*, a passenger and cargo steamer of the shelter deck type, over 490 feet in length, with a tonnage of 10,200 tons, has just been built by the well-known Belfast shipbuilding and engineering firm of Messrs. Workman, Clark & Company, Ltd., under special survey for the highest class in Lloyd's Register and to fulfill the latest requirements of the British Board of Trade for passenger service between Great Britain and India.

The vessel is fitted with the latest approved safety appliances, close spaced watertight bulkheads carried up to the superstructure deck, wireless telegraphy, and boats for all, the boats being handled by mechanically operated davits. A motor driven emergency dynamo is fitted on the boat deck,

ventilated and each is provided with a large window or side-light, electric fan, wardrobes, large mirror and porcelain wash basin with a continuous supply of fresh water. All rooms are heated by steam and lighted by electricity.

A large number of single berth, two berth and three berth cabins are provided, and communicating doors are arranged between the staterooms so that they can be used en suite if desired. A number of the staterooms are provided with beds instead of superimposed berths.

FIRST CLASS PUBLIC ROOMS

The dining saloon on the shelter deck extends nearly the full width of the ship. In this room the paneling is in the

capable of carrying on the lighting and wireless service. This dynamo also supplies power to drive an electric pump for emergency service.

PASSENGER ACCOMMODATIONS

In designing the vessel special attention has been given to the arrangement of the passenger accommodation, provision being made for 226 first class passengers in staterooms arranged amidships on the upper, shelter and promenade decks, while 92 second class passengers are accommodated in staterooms on the upper deck. All the staterooms are roomy, well

Georgian style, painted in delicate tones of ivory with gilt enrichments. Large rectangular windows at the front and sides, together with a central well overhead, afford abundant light to all parts of the room, while numerous electric fans fitted on the ceiling add to the ventilation. A broad mahogany staircase, with metal balustrades, leads from the saloon to the main entrance hall which is situated on the promenade deck above.

The lounge adjoining the entrance hall is decorated in the Louis XIV style in white and gray. This room is artistically furnished and is abundantly lighted in front and at the

Inboard Profile and Plans of Promenade and Shelter Decks

of Passenger and Cargo Steamship City of Nagpur

sides by rectangular windows and overhead by a handsome stained glass roof light.

The first class smoking room, situated at the after end of the promenade deck, is a large airy apartment tastefully furnished and decorated in oak. The wall paneling is in the Tudor style relieved by prints and engravings of the old masters. Rectangular plate glass sliding windows at the sides and a large decorative skylight overhead give ample light and ventilation.

Adjoining, and forming an extension of the smoke room, is the verandah cafe extending from side to side. The walls are stone color with teak trellis work, and boxes of flowers and large palms contribute to the decorative effect.

SECOND CLASS PUBLIC ROOMS

The second class public rooms are situated in a separate deckhouse on the shelter deck. The dining saloon is decorated in white with a dado of polished mahogany. The room is ventilated and lighted by large rectangular windows at the sides and forward end and by a skylight overhead. Immediately abaft is the entrance hall, from which a mahogany staircase leads to the staterooms.

The second class smoking room, paneled in oak, adjoins the entrance hall. A supplementary smoking room has also been provided on the after boat deck for the use of the second class passengers.

The second class lounge adjoining is pleasingly decorated in white, with a polished mahogany dado.

A large section of the promenade deck space on either side at the forward end abreast the lounge is enclosed by a steel screen in which large sliding windows have been arranged. The whole combines to form an ideal open-air lounge regardless of the weather.

CARGO HANDLING ARRANGEMENTS

For cargo handling the vessel has six hatches served by a total of 16 derricks (including one for heavy lifts) and 14 steam winches. These winches which are situated near the passenger accommodation are of the silent type, to avoid the vibration and noise generally associated with working machinery.

The cargo holds are built on the wide spaced pillar and girder principle, which gives a minimum amount of obstruction in dealing with large consignments.

PROPELLING MACHINERY

The propelling machinery, also constructed by Messrs. Workman, Clark and Company, Ltd., consists of one set of quadruple expansion engines balanced on the Yarrow, Schlick and Tweedy system, capable of developing over 6,000 indicated horsepower. Steam is supplied by five Scotch boilers fitted with forced draft and arranged to burn either coal or oil fuel. The electric power is generated by three large dynamos, which supply the lighting of the ship, the wireless telegraphy apparatus and drive the numerous auxiliary motors.

Dry Law Forces American Ship Under Registry of Panama. S. S. Resolute Now "Wet" on World's Tour

The S. S. Resolute of the United American Line, just recently built, one of the finest afloat, leaves on a world's tour under the registry of the Panama Government. Just recently the American flag was hauled down and the Panama flag substituted to enable the ship to make the world's tour without infringing America's dry law.

Tank-Motorship Oljaren, of 7,700 Tons Deadweight, Built by Aktiebolaget Götaverken, Göteborg, for the Rederiaktiebolaget Transatlantic, Göteborg, Sweden

Motorship Tennessee on Trial Trip

Twin-Screw Diesel Motorship Tennessee

Norwegian Motorship of 11,000 Tons Deadweight Capacity

Built by Burmeister and Wain for Australian Service

THE twin screw motorship *Tennessee*, just completed by Messrs. Burmeister & Wain, Ltd., Copenhagen, Denmark, to the order of Wilh. Wilhelmsen, Tensberg, Norway, is a sister ship to the *Teneriffa* and *Thalatta*, recently delivered to the same owners. The vessel is specially designed for long voyages, her oil fuel capacity being sufficient for a radius of over 30,000 miles.

The vessel is built to Lloyds Class 100 A1 special survey, awning deck with freeboard and with certificate for carrying oil fuel in the double bottom.

The leading particulars are as follows:

Length overall	444 feet 4 inches
Length between perpendiculars	425 feet 5½ inches
Breadth molded	55 feet 0 inches
Depth molded to awning deck.....	38 feet 6 inches
Depth molded to upper deck.....	30 feet 6 inches
Depth molded to lower deck	22 feet 5½ inches
Gross tonnage	7,124
Net register tonnage	4,482
Capacity of holds, about.....	570,000 cubic feet grain
Oil fuel capacity, about.....	1,300 tons
Deadweight tonnage, about.....	11,000
Draft loaded	29 feet 0 inches
Average speed at sea	11½ knots
Normal indicated horsepower.....	3,100
Normal consumption of fuel oil per 24 hours	10 tons

The hull is subdivided into eight compartments by means of seven watertight bulkheads carried up to the upper deck,

there being five cargo holds, three forward of the machinery space and two abaft the machinery space. A double bottom tank extending from peak bulkhead to peak bulkhead is fitted for the carriage of oil fuel or water ballast and in addition a deep tank for oil fuel is fitted between the shaft tunnels in No. 4 hold. The fore peak is arranged for water ballast and the aft peak for fresh water.

The ship has three complete decks of steel supported by a system of girders and wide spaced pillars in the holds, giving a good clear space for the stowage of cargo. The cargo hatches have a width of 18 feet and an average length of about 35 feet.

CARGO HANDLING GEAR

To facilitate the rapid handling of the cargo two steel tube cargo derricks capable of lifting 3 tons in single purchase and 5 tons in double purchase are fitted at each hatchway and in addition thereto there are two 2-ton derricks fitted at No. 4 hatch. For manipulating heavy lifts there is a 25-ton derrick fitted on the foremast at No. 2 hatch and a 10-ton derrick on the mainmast at No. 3 hatch, both arranged for the expeditious handling of heavy shipments.

All the cargo winches are electrically driven and are of Allmänna Svenska Elektriska Aktb. make. There are eight 3-ton winches, two 5-ton winches and two 2-ton winches for working the cargo derricks and also a heavy winch on the

M. S. Tennessee: (1) View of Main Engines from Lower Platform; (2) Starboard Side of Engine Room, Showing Pumps; (3) Port Side of Engine Room, Showing Auxiliary Engines; (4) View Between Main Engines

Main Engines of Motorship Tennessee on Test Block

deck aft fitted with extended ends and large warping drums for warping purposes.

Top of Main Engines

The windlass is of Clarke, Chapman & Company's make, suitable for 2 5/16-inch diameter chain cables and is electrically driven. The steering gear is of the electro-hydraulic Hele Shaw type from Hastie & Company, Greenock, and is controlled from the bridge by means of a telemotor. An emergency steering column is also fitted on the top of the deck house aft.

ACCOMMODATIONS

The saloon is arranged in the foremost deck house and is tastefully fitted out in polished mahogany. There are also four 2-berth passenger cabins excellently fitted out to meet

Maneuvering Platform, Looking Forward

the requirements in the tropics, likewise a special suite of apartments for the owners' private use.

The captain's accommodation consisting of bedroom and sitting room in polished mahogany is conveniently arranged in the deck house below the commanding bridge. The accommodation for the officers and engineers is fitted in the midship deck house abreast of the motor casing in spacious, well fitted out cabins. The crew are berthed aft, the sleeping accommodation is arranged below the awning deck in well lighted and well ventilated cabins for two men in each, the messrooms being arranged in the deck house above.

A 1¼ kilowatt Marconi wireless telegraph station with accommodation for the wireless operator is fitted in the deck house on the boat deck.

The culinary arrangement is in accordance with the latest practice, refrigerated provision rooms, ice generators, etc., being provided for. Electric light is installed throughout the ship.

A fire extinguishing installation, consisting of the Lux, Ltd., CO₂ system, is fitted with pipe connection to all cargo holds.

PROPELLING MACHINERY

The machinery is of Burmeister & Wain's standard type for twin screw ships. The particulars of the main engines are as follows:

2 Burmeister & Wain 4-cycle 6-cylinder Diesel motors.	
Diameter of cylinders	630 millimeters
Length of stroke	960 millimeters
Revolutions per minute	125
Indicated horsepower	3,100
Brake horsepower	2,400

The main engines are of the short stroke, forced lubricated crosshead type, with three stage compressors for supplying

the necessary injection air for atomizing the fuel oil, fitted at the fore end of the engine.

All auxiliary machinery in the engine room as well as the deck machinery is electrically driven, the necessary current being supplied by three 60-kilowatt Diesel dynamos. The voltage of the current is 220 and for lighting purposes it is transformed down to 110 volts by means of a motor generator.

Each of the generators is sufficient for supplying the necessary current under normal working conditions at sea whereas two or all three have to be started when maneuvering, with the maneuvering compressor running, or when loading or discharging cargo. A small cross tube boiler of about 100 square feet heating surface is fitted for supplying the necessary steam for the steam heating installation in the accommodation.

The trial trip was run on September 28 in the sound at Copenhagen, the following results being obtained:

Mean draft	9 feet 8 inches
Displacement	4,415 tons
Indicated horsepower, average	3,640
Revolutions per minute, average	144
Mean speed	12.6 knots

During the consumption trial, the main engines developed 3,434 indicated horsepower at 137.7 revolutions per minute, on a fuel oil consumption of 0.298 pound per indicated horsepower per hour, the net calorific value being 18,274 British thermal units including the consumption of auxiliary engines producing the necessary current for the auxiliary machinery, steering gear and electric light.

After successfully finishing her trials, the ship returned to the builders' yard to land the officials and trial trip crew and left Copenhagen on the following day on her maiden voyage to Australia.

Supply Ship for Commercial Pacific Cable Company

Staunch Steamer Designed for Continuous Service by Cox and Stevens Is Being Built by the Sun Shipbuilding Company

THE Commercial Pacific Cable Company, of the Mackay system of Commercial Cable-Postal Telegraph, has ordered a steel seagoing cable repairing and supply ship for its Pacific cable service. The vessel, designed by Cox and Stevens, naval architects, New York, is being built by the Sun Shipbuilding Company of Chester, Pa. On completion she will be stationed at Honolulu and used for the transportation of staff, supplies and equipment between the Commercial Pacific Company's station at Honolulu and Midway Island, and also for cable repairing purposes.

This new ship, which is to be named the *Dickenson* and is being built to Lloyd's classification, is of the following dimensions:

Length overall	189 feet, 9 inches
Length on waterline	167 feet, 3 inches
Beam molded	30 feet, 0 inches
Depth molded to shelter deck	22 feet, 6 inches

The vessel is of the shelter deck type, with single screw, with steel deckhouses on the shelter deck, machinery amidships, two pole masts on which steadying sails will be set, elliptical stern and cable ship bow, with the usual appliances for handling the cable forward. As the service in which she will be engaged will mean continuous and extended voyages at sea, particular attention in the design has been paid to seaworthiness and strength of construction. In addition, as the ship will be for the most part used in tropical regions, the accommodations are unusually well arranged as regards

roominess and ventilation in order that those on board may be as comfortable as possible under all conditions.

GENERAL ARRANGEMENT

The general arrangement is as follows: The machinery equipment, consisting of a triple expansion engine with cylinders 17 inches, 25 inches and 43 inches diameter and stroke of 30 inches, supplied with steam by two Scotch boilers 12 feet diameter and 11 feet long, is located slightly aft of amidships. Forward of the boiler space are the fuel oil bunkers, which are extremely large permitting an unusual steaming radius, there being in addition reserve fuel oil bunkers at the after end of the machinery space so that the ship may be properly trimmed in all conditions of loading. At the extreme after end of the vessel is an after peak tank, there being in addition a fore peak tank, as well as tankage for boiler feed and water ballast in the hold.

The rudder stock is carried straight up to the boat deck, with independent hand steering gear, the quadrant and the steam steering engine being located below deck.

Forward of the machinery space there is provided an unusually large cold storage compartment properly subdivided, forward of this again in the hold is a cable tank as well as provision for stowage of dry stores.

On the upper deck at the after end is the main dining saloon, as well as living quarters for the engineer, officers, steward and pantry attendants. Abreast the machinery space

Profile and Deck Plans of Cable Supply Ship

on this deck there is a very considerable cargo space which can be served by two cargo side ports located about amidships. The space on the upper deck forward of amidships is laid out to provide living quarters for the crew, these being all in separate rooms, each having accommodations for two men, there being in addition ample facilities in the way of wash rooms, toilets, etc., as well as a hospital.

On the shelter deck there are two steel houses, the one aft of the machinery space containing a social hall and six double-bedded staterooms with necessary bathrooms for use of passengers. The house forward of the machinery space contains quarters for the captain and deck officers, as well as for the superintendent of the company.

On the boat deck there is at the forward end a pilot house

with sleeping accommodations for the pilot, and also a wireless room containing wireless apparatus and bunk for the wireless operator.

The specifications for this vessel are extremely complete and call for the most modern type of equipment and auxiliaries. The ice machine is of the York Manufacturing Company's make, operating on CO₂ gas with brine circulation. The oil burning equipment is of the Dahl type, which is used largely on the Pacific Coast and has proven extremely satisfactory.

The vessel will be heated throughout by steam and lighted by electricity, special attention being given to securing forced ventilation in quarters as well as the best possible system of natural ventilation.

Floating Dry Dock Navigated Carrying 13,000-Ton Vessel

ON November 11, at Chester, Pa., the oil tanker *J. N. Pew* while on the dry dock of the Sun Shipbuilding Company was very seriously damaged, by the explosion of oil gas while repairs were being made upon the tanks.

The accident resulted in the loss of life of one man and the injury of 18 others, and very seriously damaged the ship, so much so, that she could not be floated off the dry dock until very extensive repairs, including the removal of interior machinery and parts, were effected.

As this company has a large hammer head crane in connection with its shipbuilding plant, the question was raised as to whether it would be possible to move the ship and dock from the berth out into the Delaware River, tow the vessel and dock some little distance up stream and place them together under the derrick.

As the local underwriters were somewhat doubtful as to this unusual suggestion, the designer of the dry dock, William T. Donnelly, consulting engineer, New York, was called on the long distance telephone in New York, and unhesitatingly assumed all responsibility, with the result, as shown in the illustrations, that the dock and ship together handled by a fleet of seven tugs was moved under the crane and returned to its mooring without difficulty.

This is believed to be the first time that such a vessel as

Bringing Floating Dry Dock and Damaged Vessel Under Hammerhead Crane at the Sun Yard

large as 13,000 tons deadweight has been navigated on the deck of a floating dry dock.

It might be added, on the designer's authority, that the stability of ship and dock was very much greater than that of the ship when floating at her usual waterline.

SYSTEM FOR NUMBERING OF STEELS.—A system of designating kinds or qualities of steel by code numbers, each of which would represent a definite specification, will be developed as a result of a recent conference of the principal producers and users of steel held at Washington, D. C.; at the call of the American Engineering Standards Committee.

INSTITUTION OF NAVAL ARCHITECTS.—The spring meeting of the Institution of Naval Architects will be opened in London on Wednesday, March 21.

Floating Dry Dock Being Towed up the Delaware River with a 13,000-Ton Vessel on Board

Stern Wheel Western River Towboat Wacouta

Steel Hull Is Stayed by Girders Instead of Hog Chains—
Propulsion Is by Twin Tandem Compound Condensing Engines

By T. R. Tarn

THE stern wheel river towboat *Wacouta*, built for the Joyce-Watkins Company, by the Dravo Contracting Company, Pittsburgh, Pa., and designed by the firm of Cox & Stevens, New York, has just been delivered to her owners after a very satisfactory trial trip at Pittsburgh. The home port of the *Wacouta* will be Paducah, Ky. She will operate out of that place to tow railroad ties on the Cumberland and Tennessee Rivers.

The principal dimensions of the vessel are as follows:

Length overall	157 feet	4 $\frac{7}{8}$ inches
Length on deck	134 feet	5 $\frac{1}{8}$ inches
Beam, molded	28 feet	0 inches
Beam, overall	28 feet	8 $\frac{5}{8}$ inches
Depth, molded	5 feet	0 inches
Crown of deck		6 inches
Mean draft	47	inches

The design of this boat includes all of those features found on the boats operating in the Monongahela River pools with

Shallow Draft Ohio River Towboat Wacouta

such modifications as were necessary to adapt her to service on the Tennessee and Cumberland Rivers.

HULL CONSTRUCTION

The steel hull is of the girder type having a modified scow bow, designed so as to permit of carrying a large amount of fuel, in order to make a trip to Sheffield, Alabama, and return without refueling. This bow, like the ordinary scow bow, is very easy to plate and gives a substantial seating for the deck fittings and towing knees. The hull is strengthened longitudinally below deck by five trusses and transversely by five watertight bulkheads.

The steel deck on the forecastle and guards is covered with Oregon fir. The planksheer is white oak. In the way of the coal bunker and the boilers the deck is cemented.

Two main deck trusses seat directly over the wing trusses in the hull and continue aft to form the support of the wheel and transmit the stresses due to operation, in conjunction with the cylinder beams.

The cylinder beams are built of plates and angles with a single web and conform to the crown and sheer of the deck. At the after transom the long beams jog to the bottom of the transom to give a greater depth to the beam and facilitate in transferring the dynamic stresses into the hull.

Recesses are provided in the cylinder beams for the pillow blocks. The after ends are fitted with a jockey beam and the portions of the main deck trusses extending aft of the splash bulkhead are stiffened by struts connected to the center ridge stringer at the boiler deck.

The main deck house and the boiler deck are of steel construction. The sides of the house forward of the main engines are formed as a part of the main deck trusses. The side capstans are located in recesses built in the sides of the house. Provision has been made for coaling the bunker from fuel flats through side doors in the house as well as from chutes or cranes from overhead. A coaming extending around the head of the boat together with inboard coamings are fitted to carry coal on the boiler deck to supplement the main bunker supply.

All of the weather plating on the boiler deck is 3/16-inch thick. The plating inside of the quarters is No. 14 gage with 2-inch by 1 $\frac{3}{4}$ -inch nailing strips placed on every beam to receive $\frac{7}{8}$ -inch tongue and groove maple flooring.

The frame of the cabin and the hurricane deck are of wood construction. Siding panels of 5/16-inch "Neva-Split" material is used. The overhang of the hurricane deck is supported by 1 $\frac{1}{4}$ -inch galvanized pipe stanchions forming the boiler deck rail.

The pilot house is of steel construction, 12 feet by 15 feet in size. The after end extends over the entrance hall to the quarters forming a seat. The steering apparatus and other gear underneath the pilot house is enclosed by a bulkhead and the remaining space is an officers' wash room.

The officers' and crew's quarters are sheathed under the carlins with stamped metal ceiling. Ventilation is provided by means of transoms under deck, both inboard and outboard. Screen doors, transom sash screens, steam heat, hot and cold filtered water for the plumbing, running ice water for drinking purposes and electric lights have been provided.

PROPELLING MACHINERY

The propelling machinery is of the twin tandem compound condensing type with cylinders 12 inches by 26 inches by 6 feet stroke operating with a steam pressure of 200 pounds per square inch. The machinery was built by the James Rees and Sons Company, Pittsburgh, Pa. The valves on both the high and low pressure cylinders are of the balanced poppet type operated by an "inside cam" motion. The "Rees" adjustable cut-off is fitted to the high pressure cylinders. The low pressure cylinders operate full stroke at all times.

Steam reversing gear is fitted together with cylinders to raise the levers and do the necessary cushioning.

Radial Stern Paddle Wheel

The wheel is 18 feet in diameter by 18 feet long with 14 buckets each 30 inches wide. The wheel shaft is a solid nickel steel forging hexagonal in section $10\frac{1}{2}$ inches across the flats with 4 cast steel flanges secured to the shaft by wedges. The journals are 10 inches in diameter by 10 inches long. The cranks are open hearth steel forgings, machined all over, and shrunk on the shaft.

BOILERS

The boilers consist of three units in one battery, 40 inches in diameter by 24 feet long, each containing five 9-inch flues of lap welded tubing. They are arranged for burning coal, hand fired, with natural draft. They are equipped with Snowden heaters, Van Dusen water gages and steam jet blowers. The safety valves are of the spring loaded type with the vents carried to the top of the pilot house.

The auxiliary boiler located in the engine room is 48 inches in diameter by 7 feet high, designed for a steam pressure of 200 pounds per square inch.

AUXILIARIES

The condenser, built by Row & Davis, is circular in section of steel plate containing 900 square feet of cooling surface. The tubes are $\frac{3}{4}$ inch in diameter of Admiralty mixture, not tinned, No. 18 B. W. G. The discharge from the condenser is run to the ash pan and discharges through the ash well.

The air pump is an independent, vertical twin beam pump having the air cylinders 14 inches in diameter, steam cylinder

Bow Capstan and Capstan Engine

ing steam scavaging pipes and quick opening gate valves, both operated from the engine room, are fitted at the intakes.

The hot well is built of 3/16-inch steel plates, 4 feet long by $2\frac{1}{2}$ feet wide by 3 feet deep, divided into four compartments by baffle plates forming skimming and quieting chambers.

Two 24-inch cast iron, tandem, double combination sand and charcoal pressure filters of the Scaife type are installed as part of the plumbing system, together with a coagulating device for introducing alum into the water. In connection with the filters a softened water tank built of 3/16-inch steel plate is installed in the engine room to provide make-up feed water storage for the boilers. The level of the water in this tank is automatically maintained and is introduced into the feed water system ahead of the air pump.

A hot water heater of the Row & Davis "Paracoil" type is installed as part of the plumbing system. This heater is capable of heating 500 gallons per hour from exhaust steam at 6 pounds gage pressure. This heater is independent of the water back in the galley stove and hot water storage tank in the galley.

The steering gear is of the regular Western River ram type, 7 inches in diameter, installed under the boiler deck over the long tiller. The pilot wheel is 10 feet in diameter and the tiller lines $\frac{3}{4}$ inch in diameter.

The electrical generating equipment consists of a 15 kilowatt, 125 volt, direct current Engberg unit, vertical enclosed engine direct connected to the generator, and a 1-kilowatt, 110-volt, direct current Moon turbine unit for standby service. An arc searchlight and a 1,000-watt nitrogen filled lamp projector, both controlled from the pilot house, are installed on the forward end of the boiler deck. At the splash bulkhead a "landing light" controlled from the pilot house is installed both port and starboard.

The steam capstan on the forecable is of the double drum, double purchase type with wood filled barrel operated by a double reversing 6-inch by 8-inch engine, located on the main deck. The side capstans have single cast iron barrels and are operated, single purchase, by double reversing 5-inch by 7-inch engines located below deck.

The refrigerating machine is of the direct expansion ammonia marine type having a capacity of one ton. The refrigerator, located on the boiler deck, contains a 40-pound ice-making set and a scuttle butt with drinking fountains located in the dining and engine rooms.

To comply with the Interstate Guarantee Regulations a "Polarstil" as manufactured by the Jewell Polar Company, having a capacity of 15 gallons per hour and a storage capacity of 200 gallons was installed.

The main steam line is $4\frac{1}{2}$ inches in diameter and the branch steam lines 3 inches in diameter. The main engine throttle is of the quick-opening type located under the boiler deck to eliminate the usual spring and branch pipe bends.

Operating Platform, Looking to Port

8 inches in diameter, all with a common stroke of 12 inches.

The circulating pump is of the centrifugal type with a side inlet, receiving its suction from the cold well. It is direct connected to a 6-inch by 6-inch vertical engine mounted on the same bed plate. The pump suction is 8 inches and the discharge 6 inches.

There are two boiler feed pumps of the vertical simplex extra heavy Worthington type with 5-inch water cylinders, $7\frac{1}{2}$ -inch steam cylinders, with a common stroke of 12 inches. These pumps are controlled by chronometer valves operated by a float in the hot well to maintain a constant level of water in the closed feed water system.

The sanitary pump is a horizontal duplex piston pump of the Worthington type with steam cylinders $5\frac{1}{4}$ inches in diameter, water cylinders $4\frac{3}{4}$ inches in diameter, with a common stroke of 5 inches.

The heater is of the Row & Davis, horizontal, steel shell, single pass, pressure type capable of heating 12,000 pounds of water when furnished with exhaust steam at 6 pounds back pressure.

The cold well is made of 3/16-inch copper, 30 inches in diameter, extending above the main deck. It is connected to combination cast brass shoes and strainers fitted to the side plating by 10-inch galvanized intake pipes. Quick open-

It is operated by means of levers and rods from a graduated quadrant on deck.

The auxiliary steam line is 3 inches in diameter, furnishing steam to the auxiliaries through a reducing valve at 125 pounds pressure.

Boiler pressure is used for the boiler feed pumps, injector, steering gear, whistle, portable syphons and the capstan engines. Auxiliary steam line pressure is used on all other units including the hull syphons.

Provision has been made at the forecastle for steam connections for attaching portable steam syphons for unwatering

lief valve is installed on this line as well as an atmospheric exhaust line to the paddle wheel for melting ice and to permit of operating the main engines non-condensing should occasion require.

OUTFIT, FITTINGS AND EQUIPMENT

The electrical installation includes plug receptacles for attaching portable hand lamps in the way of the boilers, machinery and wheel and outlets for fans and the electric iron in the laundry.

The plumbing fixtures are modern in every respect and were selected with the object of providing the crew with conveniences similar to those found ashore. All lavatories, sinks, tubs and showers are supplied with a plentiful supply of hot and cold filtered water with provision for supplying the same at all times.

Cast iron radiation is used for steam heating and is installed in the pilot house, all toilet rooms, the dining room and the forward and after cabin halls. The steam supply is taken from the main exhaust header ordinarily, with provision for using live steam if desired.

All bitts, chocks and cavils are of cast iron. The bitts are 8 inches in diameter. The chocks have 6-inch rollers and the quarter chocks and those in the way of the side capstans are tilted to give fair leads to the capstan barrels. Shackled fastenings for towing chains have been provided.

View Showing Hot Well Air Pump, Sanitary Pump and End of Condenser

the barges. Plug receptacles for attaching electric cables for use in connection with portable motor-driven centrifugal pumps have also been provided.

Mr. W. W. Watkins, general manager of the River Transportation Department of the Joyce-Watkins Company, has conducted a series of tests with several pumps of this type in order to effect a saving in the amount of raw river water required for make-up feed purposes. Unfortunately, an improved pump devised by Mr. Watkins was destroyed in the recent Chicago fire.

All of the auxiliaries in the engine room, as well as the capstan engines, exhaust into a common header. An automatic back pressure valve maintains a constant pressure of 6 pounds on this line and allows the surplus exhaust steam to enter the condenser. With this arrangement of piping the amount of make-up water for the boilers is minimized and a greater overall economy is obtained. An outboard re-

Distiller for Fresh Drinking Water

Two 16-foot wooden yawls are provided. Rollers made of 2-inch pipe are fitted at the guard and in the deck room to facilitate stowing the yawls in the deck room when desired.

The berths for the officers and crew are of white enamel steel pipe with wire springs secured in metal frames. A double berth has been fitted in the engine room aft of the tiller bulkhead for the firemen or for use as a spare berth.

The usual engine room signal bells are installed with a jingle bell in the firing alley, as well as a chestnut bell in the engine room. Cory and Sons system of engine telegraphs has been installed to supplement the above.

A combination oil and lamp locker is built in the deck room as part of the engine room bulkhead. This location does away with handling the oil in the engine room and confines a fire possibility to a more desirable place.

A very substantial locker built of steel has been provided for the engineer. A complete equipment of tools and spare parts has been provided to enable the engine room crew to make temporary or minor repairs.

Special attention has been given to the painting. The interior of the hull has been painted white in order to take as much advantage as possible of reflection. The interior of the main deck house and engine room have a finishing

coat of spar varnish. The machinery, in addition to the usual foundry filler, was given a heavy coat of lead and oil after erection and then varnished. Those parts subjected to high temperatures and not covered were given a coat of aluminum paint.

A recording pressure gage was installed on the main steam line and a recording temperature gage on the boiler feed line. A revolution counter was also installed.

The installation of superheaters was considered but the installation will not be made at present.

This machinery develops 450 indicated horsepower under ordinary service conditions when towing four wooden barges 135 feet by 26 feet when loaded to a draft of 7 feet when the river is at an ordinary stage.

The stresses in the hull structure were carefully determined by plotting the curves of weight, load, buoyancy and sheer in order to determine the maximum bending moment and its location, to effect as much saving in steel material as possible, consistent with a satisfactory fiber stress. This is a rather unusual procedure in river practice but a necessary one, especially in a shallow hull of this kind where the stresses are taken care of by trusses rather than by the usual method of hog-chaining.

Shipping Board Teaching Principles of Efficient and Economical Fuel Combustion at Navy Testing Plant

Great Competition Shown on Part of Engineers Taking Course to Obtain the Honors for Best CO₂ Readings

THE marine world has not appreciated the importance of high boiler efficiency to the same extent as have the operators of large sized stationary plants. On page 100 is given a chart showing the saving accomplished by applying stationary practice to several vessels which are representative types of the Shipping Board fleet.

The average CO₂ conditions that were found on the 13 vessels, as shown on the chart, gave 8.9 percent which shows a loss of fuel of over 6 percent. For example, if the 13 vessels had an average fuel consumption of 200 barrels per day with 150 steaming days per year, the saving would be \$36,000 in one year.

The Fuel Conservation Committee of the United States Shipping Board appreciates this situation and as part of its program has instituted the Fuel Oil School at the Philadelphia Navy Yard for engineer officers of the merchant marine. The school is located at the Fuel Oil Test Plant of the Philadelphia Navy Yard and is under the direct supervision of the Navy personnel Lieutenant Commander H. H. Norton is in charge and has very able assistants to help him carry out this work.

The Fuel Oil Test Plant is the best of its kind in the country. It has several different kinds of boilers and every means for obtaining the most complete data on steam boiler efficiencies.

SUBJECTS COVERED

One of the subjects covered in this five-day course is the problem of combustion. In order to give the engineer the principles on which to work, a lecture is given by one of the instructors in the simplest and most practical way. The things touched on are the meaning of the word combustion, excess smoke, how to remedy it, the importance of reducing the excess air to a minimum, the proper temperature at which to burn the oil, the analysis of the oil, the chemical symbols and their relation to each other.

Different types of flue gas analyzers are explained and how the chemicals are mixed to obtain the proper absorption of flue gas. At the beginning of the afternoon session, the class is assembled in the laboratory where the men are divided so that each man will have a partner and each team is given a flue gas analyzer and enough solution to make a complete charge so that each team fills its own machine

Babcock & Wilcox Boiler Equipped with Four Types of Oil Burners

Combustion Report, Tests Made on United States Shipping Board Oil Burning Vessels

ready for a test of gas. When all machines are ready for use, the class is assembled in the test plant, each team has a connection on the boiler from the uptake from where the samples of the flue gas is to be taken for analysis.

The picture shows a Babcock and Wilcox boiler with four different types of oil burners used in the merchant service. The boiler under operation is taken care of by one of the instructors who does the adjusting to the oil burners in such a way as to give a low efficiency. It is the duty of every man to readjust the burner to the best of his ability. The boilers have peep holes on all sides and with colored glasses, a man can see just how the flame is performing in the furnace. After he is satisfied that he has the best possible adjustment, he takes an analysis of the gas. Great competition takes place in this part of the course to see who takes the honors for the highest CO₂ readings. It may be stated that the percentages of CO₂ readings run between 13 and 14 percent in most of the classes at the school.

All-Steel Power Press Brake

A NEW development in the manufacture of heavy brakes has been made by the Cincinnati Shaper Company, Cincinnati, O., with the introduction of the Cincinnati all-steel press brake. This line of brakes has been designed with an open side in order to facilitate the handling of material. As most bends are made near the edge of the plate, the full length of the die-holding surface can be utilized. Thus, for most classes of work, a machine can be rated with respect to the length of the die-holding surface instead of the distance between housings, which means the use of a narrower, more rigid machine, and a saving in cost and floor space.

The bed and ram are constructed entirely of heavy steel plates and billets, which, together with cross ribs, are welded to each other, thus making what is virtually a heavy solid steel beam of box section with the metal placed to the best advantage. The housings are framed in steel plate, having

cast steel members interlocked and welded to the plates. All the revolving parts run in a bath of oil.

To meet the demand for increased production these machines have been designed to operate at a greater number of strokes per minute than has been customary in brakes heretofore. The fly wheel is mounted on high duty ball bearings having hardened steel inner and outer races. The clutch is of the multiple disk type, especially designed and developed for this particular tool and operated in oil.

These brakes are built in capacities ranging from 80 to 600 tons for working material from 10 gage to $\frac{3}{4}$ inch in thickness. The widths between housings are 6 feet 6 inches to 14 feet 6 inches; the weights 18,000 pounds to 120,000 pounds.

Cincinnati Power Press Brake with Multiple Disc Clutch

Regulations for Fire Prevention Aboard Ship

National Fire Protection Association Adopts Rules Governing Fire Hazards in the Construction and Maintenance of Vessels

THE following rules governing methods to be adopted in ship construction and maintenance for preventing the possibility of fire on board ship were prepared by the Committee on Marine Fire Hazards of the National Fire Protection Association and adopted at the recent annual convention of the association:

Throughout the following, where the word "approved" is used in designating type, construction, etc., it refers to the approval of the Inspection Department and Classification Societies having jurisdiction. No provision in these regulations is to be retroactive as regards construction.

Construction

ARTICLE I. BOILERS

1. *Lagging.* All boilers, including steam domes, shall be thoroughly covered with asbestos or other approved heat-insulating material; such covering to extend down sides below the line of grate bars. However, vertical or donkey boilers need not be covered provided all woodwork within 18 inches at sides or within 2 feet 6 inches of uptakes or breeching is covered with sheet metal over sheet asbestos.

Note: Vessels having boiler houses with steel sides, ends, and roof, will not be required to have boilers covered.

2. *Floors.* All fire-room floors shall be covered with iron plate or at least 2 inches of cement, or other approved material. At least $\frac{3}{4}$ -inch asbestos board or 1-inch plastic asbestos or equivalent shall be laid over all woodwork under a fire-room floor.

3. *Foundations.* The floor under the grate bars of all externally fired or leg boilers shall be of brick or cement at least 6 inches thick, vented by the insertion of old tubing laid horizontally, or its equivalent, under which shall be at least $\frac{3}{4}$ -inch asbestos board or $1\frac{1}{2}$ -inch plastic asbestos or equivalent covered with sheet metal. The floor under vertical boilers, if laid on a wood deck, shall be of brick or cement or other approved material, similarly vented, at least $2\frac{1}{2}$ inches thick, extending out in front at least 3 feet; or, if less, shall have a fire-resistive coaming around said floor projecting at least $2\frac{1}{2}$ inches above it, or be covered by a metal pan with projecting edges. On all such floors, under the brick or cement there shall be at least $\frac{3}{4}$ -inch board or 1-inch plastic asbestos or equivalent covered with sheet metal.

4. *In Way.* Where coal and wood, or stores, or cargo of any description, except oil, are carried or may be carried alongside of boilers, a partition shall be built at least 4 inches clear, to prevent anything being placed next to the boilers; and under no circumstances may anything be placed between such partitions and the boilers. If anything is or may be carried near the back ends of boilers, similar partitions or bulkheads are to be fitted, but these shall be at least 2 feet distant from boilers, and space between them and boiler kept clear and clean. Under no circumstances may a wood platform, locker or grating be fitted over top of any boiler nearer than 12 inches, and no lines, clothes, or other combustible articles be laid over or alongside of boilers.

5. *Ash Guards.* A steel coaming at least 12 inches high shall extend from the front of all boilers to side partitions to prevent coal or ashes getting into wings.

6. *Drip Pans.* Where oil is used for fuel, on leg or externally fired boilers there shall be a drip-pan of heavy iron under the fire boxes to catch all drip. Where wood is used for fuel, a water pan shall be fitted under the grates, and a partition or metal screen erected to prevent cinders or sparks being blown into the woodpiles. In no case may the wood be stacked against the boiler.

7. *Casings.* The construction of the house or casing over and around the boiler should be of such nature that hot air or gases cannot be pocketed at any high point; but if such exist, suitable vent louvers shall be cut in sides of house or casings to provide a circulation of air.

8. *Bulkheads.* Screen bulkheads between fire room and engine room should, where possible, extend down to the tank top or shell of the vessel in order to form a fire wall between engine room and fire room bilges. Where oil burning equipment is installed, these bulkheads should be made oil-tight to at least two feet above the tank top and bilges to prevent any oil reaching the engine room bilges and tank top.

ARTICLE II. STACKS

9. *In Way.* Where a smoke stack passes through a wood deck, the woodwork should be cut away at least 12 inches from the stack and the wood faced with a metal collar over sheet asbestos; but where the construction of the vessel will not permit a space of 12 inches, there shall be an opening at least 4 inches wide around stack; this opening to be completely faced with a metal collar extending at least 6 inches above roof and 6 inches below same, and the carlins and roof on under side around opening, covered with sheet iron extending back radially at least two feet. Sheet asbestos at least $\frac{1}{8}$ inch thick shall be placed under all metal.

10. *Umbrellas.* The bottom of the flange of the umbrella around stack shall be higher than the top of the flange around the opening in the deck, leaving a clear horizontal space for the escape of the gases or else a perforated coaming shall be used.

11. *Wood Burners.* The stacks of all vessels using wood for fuel shall be fitted with spark arresters.

ARTICLE III. STEAM PIPES

12. *Lagging and Clearances.* All main and auxiliary steam pipe lines shall be thoroughly covered with asbestos or other approved material if within six inches of woodwork; and where such steam pipes pass through woodwork, they shall be fitted with a proper metal collar and the woodwork cut away or protected in an efficient manner.

ARTICLE IV. BUNKERS AND HOLDS FOR COAL

13. *Vents.* Ventilation of all hold, wing, and 'tween-deck bunkers shall be provided for by pipes or trunks leading to outside atmosphere.

14. *Temperature Testing.* Reserve bunkers and holds shall be provided with sounding trunks so that internal temperatures may be read as required.

ARTICLE V. BUNKERS AND TANKS FOR OIL

15. *General.* The storage of oil shall be restricted to cellular double bottom, hold, deep, peak, bunker, settling and other tanks specially constructed for this purpose. These compartments and tanks shall be fitted with approved bulkheads, sub-divisions or swash plates. They shall be so strengthened as to satisfactorily withstand the stresses brought upon them in a sea-way when partially filled; and if separate from the hull, shall be properly braced and secured thereto by chocks or clips riveted to both tank and foundation. The scantlings and riveting shall be in accordance with the requirements of the American Bureau of Shipping, or approved equivalent, for vessels and tanks carrying oil in bulk.

16. *Location.* Fuel tanks should not be located on deck; but if such an arrangement is necessary, the installation must be approved.

In order to avoid as far as possible uncontrollable flooding in event of accident; the amount of piping under static head of fuel oil should be reduced to a minimum consistent with the design of the system.

17. *On Wooden Vessels.* On wooden vessels a lead lining shall be placed under tanks which are separate from the hull. Lining shall be not less than 8 pounds per square foot, laid over a coaming at least 6 inches high and drained to a sump fitted with independent stripping suction at the lowest point. These tanks shall be not less than 18 inches from boilers at all points except the back where they shall be at least 24 inches distant.

18. *Tests.* All oil storage compartments and tanks shall be tested by a head of water in accordance with the requirements of the American Bureau of Shipping or approved equivalent.

19. *Painting.* All oil tanks, compartments, and bunkers shall be thoroughly coated on the outside with a suitable non-flammable and rust-resisting material.

20. *Vents.* An independent, permanently open, iron vent pipe terminating in a goose neck or approved automatic valve in the open air and above the upper deck shall be provided for every oil tank, compartment or bunker. Vent openings shall be screened (40 by 40 non-corrodible mesh) and of sufficient freeing area to permit unrestricted inflow of liquid during the filling operation (in no case less than two inches in diameter) and accessible for examination and removal.

Vents shall terminate well above the top of the fill pipe; or, if tight connection to the tank is made in the filling line, at a point one foot above the level of the top of the highest reservoir from which the tanks may be filled and never less than 3 feet, measured horizontally and vertically, from any porthole, window or other similar opening.

21. *Fill Pipes.* On tankers, fill pipe deck terminals shall be kept closed when not in use; and on other oil burning vessels, they shall be so designed as to make access difficult by unauthorized persons.

22. *Manholes and Hatches.* Manhole and hatch covers of oil tanks on all vessels shall be designed to fasten securely; and on oil burning cargo or passenger vessels shall be bolted, dogged or locked, and labeled or painted a distinctive color designating them as openings to oil tanks.

23. *Drainage.* Adequate means shall be provided by wells or gutter-ways and sparring or lining, to prevent any leakage from the fuel oil compartments coming into contact with cargo and to ensure that any such leakage shall have free drainage into the limbers or wells. In machinery spaces, such leakage shall be confined by gutter-ways to bilge cofferdam spaces next to tank bulkheads; and these spaces shall be drained independent of the main bilges by stripping suction to a suitable pump.

24. *Double Bottoms.* If double bottoms under holds are used for carrying oil fuels, the ceiling shall be laid on transverse battens, having at least a two-inch air space between the ceiling and tank top and permitting free drainage from tank top into the limbers. The method of venting this space shall be subject to approval.

25. *In Way.* A clearance between oil tanks and boilers, boiler casings and breechings of not less than 24 inches at the back ends of boilers and 18 inches elsewhere shall be arranged; and all structures giving off heat shall be effectively insulated if within 18 inches of any oil tank or compartment.

26. *Cofferdams.* The practice of constructing a cofferdam between deep fuel tanks and cargo tanks or storage compartments is recommended for all oil burning steam vessels. Such construction is considered unnecessary on motor vessels using fuel other than gasoline. On steam vessels burning oil of a flash point lower than 150 degrees F., closed cup, there shall also be a cofferdam between fuel bunker and fire-room compartment. The space enclosed by cofferdams shall be vented in accordance with the provisions of section 20.

ARTICLE VI. OIL BURNING AND HEATING SYSTEMS

27. *General.* It is strongly recommended that systems whereby oil is pumped from tank to the burners be used; but in cases where pumping system is deemed impracticable and the use of gravity feed is desired, special permission shall be obtained for installation and detailed plans submitted and approved.

Pumps shall be in duplicate, of an approved design, well secured against leaks under a test pressure 50 per cent in excess of the designed pressure of the system carried.

Whether pumps are located inside or outside of the fire-room, gear shall be installed for operation from deck of stop valves on each tank and throttle valves on both service and booster pumps. This provision does not apply to fuel pumps on motor vessels.

On steam vessels burning oil of a flash point lower than 150 degrees F., closed cup, the pumps handling such oil shall be located in a compartment separated from the rest of the machinery space by gas-tight bulkheads and accessible therefrom only by a gas-tight door.

The piping and spindles of fire-room controls shall be made gas-tight where they pass through the pump room bulkheads.

This pump room shall be provided with induced ventilation always sufficient to reduce the pressure therein slightly below that in the compartment from which entry is made. The provision of section 20 shall also be observed.

28. *Oil Level Indicating Devices.* Devices for ascertaining or indicating the oil level in storage and service tanks shall be provided. Use of gage glasses is prohibited except on motor vessels using fuel other than gasoline. Sounding pipes and spring loaded trycocks normally closed are approved. It is recommended that, where practical, a compression chamber connected by air piping to a mercury gage be installed, with gage and annunciator mounted on a board to indicate and signal audibly when the contents of each tank reaches a predetermined level. Other methods of meeting this provision are subject to approval.

29. *Heating of Tanks.* Where it is necessary to heat oil in storage tanks in order to handle it, the heating shall be done by means of properly installed coils or other approved system using only steam or water. Thermostatic control and thermometer are recommended for all heating devices.

30. *Heaters, Other Than Those for Tanks.* Heaters shall be of substantial construction with oil-tight joint. Only steam, water or approved electric device may be used for heating. A $\frac{1}{2}$ -inch relief valve, set at 400 pounds per square inch and discharging to the suction line or tank shall be fitted on the oil side of all heaters to prevent the accumulation of excess pressure when the heater is shut down, due to expansion of the oil caused by leaky steam supply valve or failure to shut off the steam supply.

31. *Burners and Air Registers.* Drip pans shall be fitted under each burner. Air registers should include provisions for the inspection of burner tips while register is in use. Registers should permit ready adjustment in area of air openings.

Burners shall be fitted in the registers so that they may be shut off, readily removed, or cleaned independently of each other.

ARTICLE VII. FUEL OIL PIPING AND FITTINGS

32. *Tank Piping.* A piping system for fuel oil storage tanks separate and distinct from other piping in the vessel is recommended; but an interchangeable system providing a method which precludes the possibility of a mixture of ballast water and oil may be used subject to approval.

33. *Type and Material.* All piping and fittings comprising the fuel oil system between pumps and burners shall be of the extra heavy type. Seamless drawn pipe is recommended for all pressure lines, but in installations burning oil of a flash point lower than 150 degrees F., closed cup, such piping shall be seamless drawn. No pipe less than $\frac{3}{8}$ inch internal diameter may be used. Unions, if used in place of right and left couplings, shall be of an approved type.

34. *Installations.* All piping shall be run as directly as possible without sags and so installed that, where possible, pipes pitch toward supply tanks without traps, and provisions shall be made for expansion, contraction, jarring and vibration.

35. *Test.* Oil piping between pumps and burners shall be tested and proven tight at a pressure of not less than 500 pounds per square inch. All joints and fittings in the pressure piping shall be kept oil-tight under service conditions.

36. *Protection.* Piping shall be exposed to sight wherever possible to insure prompt detection of leaks, and shall be protected against mechanical injury in an approved manner.

Pipes extending above the floor, particularly risers to furnaces, shall be effectively cased or jacketed to prevent loosening or breakage.

Fill and vent pipes shall be protected in an approved manner against mechanical injury.

37. *Valves.* All valves shall be of an approved type. Shut-off valves shall be located as follows: On both sides of any strainers installed in pipe lines; in discharge and suction lines at the pumps; in discharge and suction lines to any tank, directly on the tank; and in branch lines to burners.

A pressure relief valve shall be installed in the discharge line to burners and so arranged as to return surplus oil to the suction line.

38. *Strainers.* Duplex strainers shall be fitted in the suction of both booster and fuel oil service pumps; provided, however, that if booster pumps are used to deliver oil to the suction of the service pumps, the strainers need be fitted only in the booster suction. Strainers shall be so designed that one side can be cut out for cleaning while the other is the service.

ARTICLE VIII. LIGHTING

39. *Lamp Rooms.* All wooden oil and lamp rooms or lockers shall be completely lined with sheet metal nailed over asbestos at least $\frac{1}{4}$ inch thick, and nailing protected in accordance with National Fire Protection Association standard for fire door construction. No openings except doors or covers will be permitted.

40. *Oil Lights.* All oil lamps shall have metal bodies and, except hand lanterns, shall be kept in brackets well secured or suspended and stayed. They shall be secured in the brackets by an approved device for holding them in place, and shall have metal shields over them. Hand lanterns when suspended shall be secured by clips. It is recommended that solidified fuel, being safer and smokeless, be used in lamps, where possible.

41. *Electric Lights.* On all vessels using electric lights, the wiring for same shall be run in armored cable or metal conduit in the following locations: In holds, in engine and boiler rooms, in bunkers, in cargo spaces or other places where cargo is carried, and where wiring is run outside. Switchboards, fixtures, wiring and all other electric apparatus shall be installed in accordance with the rules of the National Electric Code.

Note: The "Recommended Practice for Electrical Installations on Shipboard," issued by the American Institute of Electrical Engineers is recommended as a guide for electrical installations. This is consistent with the requirements of the National Electrical Code and goes more into detail both with regard to good practice as affecting fire hazards, and also with regard to many other questions of installation, maintenance and operation having bearing on durability and safety on vessels.

ARTICLE IX. GALLEY AND HEATING

42. *Ranges.* The galley range shall be securely fastened to the deck, at least 1 inch air space or approved equivalent insulation being provided between the bottom of range and deck; and, if galley floor is wood, range shall have metal under it extending out in front at least two feet. If range is within 18 inches of a wooden bulkhead, such bulkhead shall be covered with sheet metal over asbestos at least $\frac{1}{4}$ inch thick. All smoke-pipes or stacks passing through wooden bulkheads or partitions shall be fitted with a proper metal collar and have woodwork cut away. Galley ranges shall have metal hood over them or have the ceiling protected with sheet metal over asbestos at least $\frac{3}{8}$ inch thick. No wooden warming racks over stoves will be permitted.

43. *Steam Heat.* A complete steam-heating plant on steam vessels is recommended. All steam-heating pipes and radiators shall be kept clear of woodwork. Where radiators are adjacent thereto, a metal shield shall be fitted behind each with $\frac{1}{4}$ inch air space between shield and woodwork.

44. *Stoves.* The use of stoves is discouraged; but where used, they shall be securely fastened to the deck, at least 1 inch air space being provided between bottom of stove and deck; and shall have sheet metal on the floor under them extending out on all sides at least 12 inches. If stove is within

18 inches of a wooden bulkhead, such bulkhead shall be protected with sheet metal over asbestos at least $\frac{1}{4}$ inch thick. All smokepipes or stacks passing through wooden bulkheads or partitions shall be fitted with proper metal collars and have woodwork cut away; and all woodwork within 8 inches of smokepipe shall be protected with sheet metal over asbestos at least $\frac{1}{4}$ inch thick.

Appliances

ARTICLE I. GENERAL

45. In addition to fire fighting equipment required by rules of United States Steamboat-Inspection Service, it is recommended that small gear such as smoke helmets, life lines, slickers, and gloves, be provided and kept in approved convenient places.

ARTICLE II. HOSE AND COUPLINGS

46. Hose shall be of an approved type. All hose couplings and fittings shall be in accordance with national standard of the National Fire Protection Association.

ARTICLE III. SPRINKLERS

47. *Features of Design.* To improve and encourage the use of sprinkler fire protection aboard ship, it is recommended that the following features be incorporated in any system.

The system and apparatus should be as simple and inexpensive as possible; and, so far as applicable to marine work, should comply in detail with regulations of the National Fire Protection Association.

The design should be such that it would operate only in case of fire, and not subject the ship or its contents to consequential damage due either to freezing, accidental operation, breakage or to any causes other than fire. To this end, the sprinkler pipes should preferably be empty and under atmospheric pressure; but served by fire pumps of ample capacity. The control should be dual, both manual and automatic; but it is recommended that the automatic feature be attained only through the use of a thermostatic control or other system which would prevent release of water except in the presence of heat.

48. *Location.* Automatic sprinkler equipment is recommended in cabin, store, crew and passenger spaces; and optionally, in cargo and machinery spaces, owing to the usual impracticability of stowing cargo or arranging machinery to all proper distribution of a sprinkler equipment.

ARTICLE IV. SMOTHERING DEVICES

49. *Steam Jets.* Steam jets controlled by master valves in accessible location are considered a satisfactory means of fighting fires in the cargo spaces of a vessel in the present stage of development of extinguishing apparatus. The size and number of steam smothering pipes called for herein are based on a steam pressure of 100 pounds. These sizes are suitable for higher pressure than 100 pounds, but for lower pressure they should be proportionately increased.

(a) Each compartment shall have a branch with steam jets of sufficient size to fill it in not more than fifteen (15) minutes.

(b) The main supply pipe from boilers on steam line shall be of sufficient size to supply 50 percent of the total volume of all the cargo spaces at one time.

(c) Main supply line on deck, running forward and aft, shall be of equal area at any point to the combined area of the branches taken from same, but at no point need its area be in excess of the main supply from machinery space of 50 percent of the area of all the branches in the vessel.

(d) The orifice area of the steam jets supplied by any branch pipe shall be at least equal to the cross sectional area of such pipe; that is, the end of the pipe may be left open, or it may be closed and a number of openings made in the pipe, the combined area of which shall be at least equal in area to the open end of the pipe.

(e) Maximum size of branch steam pipe to any cargo compartment shall be one and one-half inches ($1\frac{1}{2}$ inches) nominal diameter.

(f) Cargo spaces requiring more steam than would be supplied by a one and one-half inch ($1\frac{1}{2}$ inch) pipe shall have additional branch pipes and steam jets.

(g) Minimum size of branch pipe to any cargo compartment shall be one inch (1 inch) nominal diameter.

(h) Minimum size of branch pipe to lamp rooms, paint lockers, etc., shall be three-quarters inch ($\frac{3}{4}$ inch) nominal diameter.

Where

L—Length of compartment, in feet.

B—Breadth of compartment, mean, in feet.

H—Depth of compartment, mean, in feet.

D—Diameter of pipe required, in inches.

Then

$$D^2 = \frac{L \times B \times H}{30,000}$$

Or in accordance with the following table:

Values of $L \times B \times H$	Connection No. of Inlets	Size of Inlets Inside Diameter, Inches
30,000	1	1
46,000	1	$1\frac{1}{4}$
67,000	1	$1\frac{1}{2}$
94,000	2	$1\frac{1}{4}$
135,000	2	$1\frac{1}{2}$
203,000	3	$1\frac{1}{2}$

Size of main steam pipe

$$D^2 = \frac{\text{Summation of all } (L \times B \times H)}{60,000}$$

50. *Gas.* The use of inert gas, such as carbon dioxide for extinguishing or preventing fire may be applied to holds, bunkers, and other closed compartments not normally accessible to crew or passengers; but, on account of danger to life, the use of gas of this character shall be restricted to such spaces. On motor vessels and those equipped with insufficient boiler capacity to permit effective application of steam smothering, the installation of a gas system, subject to the foregoing restrictions, is recommended.

ARTICLE V. FIRE ROOM APPARATUS

51. *On Coal or Wood Burners.* In addition to regularly prescribed hose and extinguishers in each fire room; steam fire hose, coupled to the injectors and of sufficient length to reach all parts of fire room, should be provided.

52. *On Oil Burners.* In fire rooms with oil burning boilers a sufficient number of 2½-gallon foam-type chemical fire extinguishers shall be provided; and a box of dry sand with a scoop may also be supplied. It is also recommended that an extinguishing system be piped to inaccessible parts of fire room, such as under boilers and floor plates and in bilges. A foam or steam-smothering installation is approved for this purpose. Either an automatic or manual system or a combination of both may be used, but control of all manual systems should be from both inside and outside of the fire and engine room spaces. The type, number and location of extinguishers and layout of pipe lines and nozzles shall be subject to approval.

ARTICLE VI. EXTINGUISHERS

53. *General.* Hand chemical extinguishers should be distributed through all parts of the vessel accessible to crew or passengers, and the selection and distribution governed by the regulations of the National Fire Protection Association Committee on Field Practice. All extinguishers should be of types approved by the United States Steamboat-Inspection Service, and on the list of inspected mechanical appliances issued by the Underwriters' Laboratories.

ARTICLE VII. DETECTION AND ALARM

54. *General.* It is recommended that on passenger and cargo vessels, except tankers, pipes for detection of smoke or fumes be led from holds, bunkers and inaccessible parts liable to fires, to the bridge, engine room or other points where they may be readily observed; and that vessel be equipped throughout with a fire alarm system approved as to type and installation.

Operation

ARTICLE I. GENERAL REQUIREMENTS

55. In addition to the United States Government rules as to operation, quarters, stowage and packing of hazardous cargoes, etc., the following are recommended or required as noted:

ARTICLE II. DRILLS AND QUARTERS

56. It is recommended that certain members of the crew be designated as fire wardens and trained to special duties, such as use of smoke helmets and extinguishing apparatus, life saving, etc.; and that some form of compensation or privilege be accorded the men so designated.

ARTICLE III. CARE OF COAL BUNKERS

57. Care shall be taken that all vents are clear when bunkering is completed. In case of vessels having wooden bunkers using soft coal for fuel, same shall be thoroughly cleaned out at least once every sixty days while vessel is in commission. The coal bunkers of all vessels shall be cleaned on going out of commission or being laid up for over sixty days, making sure that all coal dust and rubbish are removed. Special care shall be taken in cleaning shelf pieces.

ARTICLE IV. PAINTING

58. Care shall be taken to ventilate, so far as possible, all confined spaces where paint containing inflammable ingredients is being used or stored, and naked lights in such spaces are prohibited. Paint lockers shall not be located in close proximity to boilers or stacks.

ARTICLE V. FUEL OIL REQUIREMENTS

59. *Flash Point.* These regulations are intended to apply generally to those oil burning equipments using only liquids having a flash point above 150 degrees F., closed cup tester; however, the necessity, under certain conditions, of burning fuel oil of lower flash than this point is recognized and additional requirements for the use of such oils are noted in sections 26, 27, 33 and 78 of these regulations. No untopped oil shall be used for fuel except in accordance with these additional precautions.

60. *Flash Test.* In determining the flash point, either Elliott, Abel, Abelpensky or Tag closed testers shall be used, but the Tag closed testers (standardized by the United States Bureau of Standards) shall be authoritative in case of dispute. All tests shall be made in accordance with the methods of tests as adopted by the American Society for Testing Materials.

ARTICLE VI. LOADING AND BUNKERING OF OIL

61. *Preliminary.* Before commencing to load oil, all signal bells, gongs, etc., shall be tested to insure working condition.

62. *Oil Hose.* Hose used for filling or discharging shall be of the flexible metallic type equipped with oil tight flanged joints or some other approved coupling device for the purpose of preventing rupture of connections. The inner metallic lining of such hose shall be effectively grounded against possible charge of induced electricity.

63. *Hatches and Manholes.* No double bottom, deep, peak or independent tank manhole or hatch opening shall be used for fuel oil filling purposes, except on tankers where trunk hatches extend to weather deck and proper warnings are posted while operation is underway.

Hatches on tankers shall be kept closed during loading or discharging except when in use for such purposes. Tugs or other steam vessels shall not be allowed alongside when oil tank hatches are open.

64. *In Way.* While oil is being received or discharged, no open lights or fire, smoking, or electrical apparatus liable to spark shall be permitted within 50 feet of an opening in any oil hose, tank or compartment containing a tank or vents.

65. *Galley.* If practicable, galley fires in tankers shall be extinguished during loading or discharging; otherwise, openings to the galley shall remain tightly closed.

66. *Lights.* Loading or discharging should, as far as possible, be carried on in the day time. When carried on at night, no lights shall be permitted on the deck. Flood lighting or lights in clusters suspended in the rigging well above the deck are approved. Wires shall not lie on or drag across the deck. The use of portable connected electric lights on deck of tankers or in tanks or pump rooms of any oil burning or oil carrying vessels is prohibited.

ARTICLE VII. TANK CLEANING AND DISPOSAL

67. *Dry Dock.* When vessels containing fuel oil of any kind are in dry dock, care shall be taken that no oil drains onto the dock. Should it be necessary to remove oil from tanks, precautions shall be taken to prevent any oil escaping to form an accumulation of vapor or oil on or around the dock. Should any oil so escape, it shall be skimmed and disposed of ashore.

68. *In Port.* Tankers or other vessels carrying water for ballast in fuel oil compartments or double bottom, shall not discharge such water ballast into rivers or harbors or adjacent to ships or docks.

69. *Tank Freeing.* Tanks, valves and pipe lines throughout the vessel shall be freed of vapor in accordance with the regulations of Appendix A before repairs in way are undertaken.

ARTICLE VIII. PRECAUTIONS ON OIL BURNING AND TANK VESSELS

70. *Inspection.* The inside of oil compartments and tanks should be inspected at least annually; and bulkheads separating such compartments from others should be examined for leaks during inspections and whenever oil is taken aboard.

71. *Tank Readings.* Gage valves or cocks fitted to the storage or settling tanks shall be kept closed, except when a reading is to be made; and shall be closed immediately upon completion of the reading.

72. *Dampers.* Dampers in stacks and up-takes shall always be kept sufficiently open while burning oil, in order to prevent dangerous accumulations of vapor in the furnace or breechings with consequent blowing back into the fire room.

73. *Tests.* Whenever that part of the oil system subject to pressure has not been in use for a week, or after joints in the same have been remade, it should be tested cold under a pressure at least equal to the working pressure; and a careful inspection made for leaks before fires are lighted. All fuel oil fittings should at all times be kept in working order; and the oil slats, drafts, and valves should be frequently moved when not in use to insure such condition.

74. *Vents.* Frequent inspection shall be made to insure that wire gauze screens in vents are clean and intact.

ARTICLE IX. FURNACES AND FIRES ON OIL BURNING AND TANK VESSELS

75. *Re-Lighting.* In the event of oil accumulating in the furnace, such as might be caused by sudden extinguishing of the burners, the vapor must be blown out and drip oil removed before burners are again lighted.

76. *Fire Room.* Oil shall not be permitted to accumulate in the oil boxes, openings of furnaces, bilges, or on the floor plates; and no lighted material shall be allowed access to the bilges. After fires are out, bottoms of furnaces shall be examined and any oil remaining removed. In case of leakage of oil system in fire room, immediate action shall be taken to shut off the oil supply.

77. *Galley.* On tankers, when coal burning galley fires are lighted, the use of waste, chips, oil, etc., shall be prohibited, and only a limited amount of wood covered with coal shall be used. Every precaution shall be taken to prevent sparks or flame from blowing out the smokepipe.

78. *Low Flash Oil.* When oil of a flash point lower than 150 degrees F., closed cup, is used, attention is called to the extra hazard incurred by permitting any such oil to escape and gas therefrom to form an explosive mixture with the inclosed atmosphere of fire room or compartment. Rules for handling, heating and burning of such oil should be laid down by the superintending engineer according to his best judgment and experience, and no deviation therefrom on the part of engineering subordinates allowed. This general regulation is promulgated pending the results of further investigation of low flash oil hazards.

79. *Matches.* The use aboard tankers or oil burning ships of other than strike-on-box matches is prohibited.

ARTICLE X. CARGOES

80. *General.* A comprehensive treatment of the subject of hazardous cargoes and their packing and stowage is beyond the scope of these regulations; but specific cases for stowage of such cargoes may be referred to regulations of the following authorities: Interstate Commerce Commission for transportation on railways of United States as contained in Bureau of Explosives Pamphlet No. 9; United States Steamboat Inspection Service, as contained in Revised Statutes No. 4472, and special bulletins; and the Rules of the American Steamship Owners' Protection and Indemnity Association; which regulations the committee recommends adopting in full, pending regulations to be drawn by the Interstate Commerce Commission covering marine transportation as authorized by Act of Congress in March, 1921.

Appendix—A

Regulations for Freeing Oil Tanks, Bunkers and Compartments of Flammable and Explosive Vapors Previous to Entering for any Purpose or Making Repairs on Oil Burning or Oil Tank Vessel.

1. For the purpose of these regulations, an "explosive or inflammable liquid" is defined as one which when vaporized and mixed with air in proper proportions, is flammable or explosive.

2. No repairs of any kind shall be made to any tank, compartment, bunker, or other container or space, previously containing explosives and flammable liquids, in any vessel until the requirements hereinafter outlined have been complied with.

At sea or in ports where the means of carrying out these requirements are not available and the safety of the vessel necessitates emergency or temporary repairs, such repairs may be made to permit the vessel to proceed to the port of destination.

3. The process of freeing such containers of vapor shall be as follows:

4. (a) Tanks shall be closed and live steam blown into the tanks or space to be cleaned and all pipes leading thereto or therefrom for a period of time to be governed by the condition and the nature of the oil carried. Vent pipes shall be proved and left open.

Inasmuch as the time for steaming will be determined by the foregoing, no definite rule is laid down to cover all contingencies, but the following table is recommended as covering average general conditions:

Where:

L—Length of compartment in feet.

B—Breadth of compartment in feet.

H—Depth of compartment in feet.

The time of steaming is arrived at by taking the number of hours given in the table under the actual size of steam connection corresponding to the value given for $L \times B \times H$, or the volume in cubic feet of the compartment to be steamed.

Size of Steam Connection at 100 pounds pressure

Value of $L \times B \times H$ Not Exceeding	1 Inch Hours Steaming	1½ Inch Hours Steaming	2 Inch Hours Steaming
30,000	20	14	10
40,000	26	18	13
50,000	32	22	16
60,000	38	26	19
70,000	44	30	22

The above calculations are based on a steam pressure of 100 pounds per square inch.

Note: In steaming tanks the last one-fifth of the steaming period should be carried out with manhole plates or tank lids opened to the atmosphere.

(b) Upon completion of the operation above noted the tank or space so treated shall have all manhole plates and covers or other openings removed and thoroughly ventilated by means of wind sails, forced or induced draft.

(c) Following this process, specimens of air shall be taken by a competent chemist, whose ability and reliability shall be certified to by the American Bureau of Shipping. These samples shall be analyzed or tested by him, and if the tank or space from which samples have been taken still contains explosive or flammable gases, such further steaming, and/or ventilating shall be carried out as recommended by the chemist. After such steaming and/or ventilating, further samples shall be taken by him and analyzed or tested; this process to continue until the tank is certified by the chemist to be free of all explosive or flammable gases.

5. (a) In cases where a tank or space to be repaired adjoins another tank or space, no repairs shall be permitted unless adjacent tanks or spaces are freed of vapor as provided in paragraph 4 (c).

In cases where a vessel having carried cargo of flash point below 150 degrees F., closed up, is to undergo repairs at a shipyard, or alongside a wharf, all the vessel's compartments or tanks containing inflammable gases, with the exception of the ship's bunker tanks, shall have been steamed and ventilated for at least twenty-four hours prior to delivery to repair yard, and all tanks in which any repairs are to be made, and tanks adjacent to same, shall have been freed from explosive or flammable gases as provided in paragraph 4 (c); the balance of the tanks shall be sealed tight.

The only exception to this rule shall be, where the repairs to be made are confined exclusively to the engine and fire room spaces or/and to quarters, or where vessel is placed on dry dock merely for the purpose of cleaning and painting under water body and overhauling sea valves, in which case it will only be deemed necessary that all tank lids and/or covers shall be sealed tight.

(b) Repairs may be made to equipment, etc., in pump room without freeing from gas any space on the vessel other than pump room space.

(c) No repairs necessitating the use of fire or of tools liable to cause sparks by contact with metal, may be made to the decks of a vessel, except by special permission of the certified chemist, without first freeing adjacent tanks from explosive or flammable gases.

6. (a) The tests herein prescribed and required shall be made as provided by a competent chemist whose ability and reliability shall be certified to by the American Bureau of Shipping.

(b) Where oil or sediment liable to regenerate explosive or flammable gases has not been entirely removed from the tank in which repairs are to be made, the above mentioned certified chemist shall, when delivering to the interested parties the gas free certificate, required by these regulations, advise them as to the necessity, if any, of further testing of said tanks while undergoing repairs, and such tests shall be made before proceeding with repairs in the tanks.

7. While repairs or cleaning operations (but not air sampling) are under way, a current of air under forced or induced draft shall be continuously circulated through the tank or other space.

Note: Ventilation may be accomplished by wind sails, draft forced or indirect by a blower, pump or fan. It is recommended that compressor or other air unit have a minimum capacity of not less than 400 cubic feet of free air per minute.

8. (a) No open lights or fires shall be permitted within 50 feet of an opening in any tank or space not conditioned for repair as previously outlined. Lights carried into such tanks shall be electric of a type approved by the Bureau of Mines for use in gaseous mines. Electric hand flash lights may be used as accessories.

Note: If possible, all repairs should be made during daylight. Portable connected electric lamps are prohibited. Self-contained electric battery lamps may be used.

(b) No repairs of any kind shall be made until the foreman is provided with a permit signed by the superintendent. This permit shall not be issued until tank or other container has been freed of vapors as previously outlined, and shall be carried by the foreman in charge, and shown upon request to anyone in authority.

Note: It is recommended that a permit form similar to the following be used for this purpose:

Fire Permit No. Date.....
Permission is hereby granted to.....
(Foreman) to make repairs, including any repairs necessitating the use of fire on.....
as follows.....

Subject to the following conditions:

Fire to be kept as low as possible. All precautions to be taken to prevent sparks from flying. When finished using for the day, fire must be extinguished and coals thoroughly wet.

Approved

.....Supt.....

9. Should any emergency require the entering of a tank, bunker or other space before it is thoroughly free of vapors, the person or persons so entering shall be protected by a gas mask approved for such purpose by the Underwriters' Laboratories in accordance with tests prescribed by the United States Bureau of Mines. A rope shall be attached to the body of each man at work in the tank and each rope held by two strong men outside the tank. Persons at work within the tanks shall be under constant attendance, so that upon any indication of trouble they may be withdrawn.

Oxygen breathing apparatus may be worn for a period of not more than 20 minutes, after which it shall be aired in fresh air for not less than 6 hours before further use. Wearers of respiratory apparatus shall be instructed and trained in their use before being permitted to enter a dangerous atmosphere.

The Isherwood System of Ship Construction Shows Remarkable Growth

THE progress returns for the "Isherwood" System up to the end of 1920 showed some remarkable figures regarding the number of orders placed, but a great falling off in the shipbuilding industry has taken place since that time which is reflected in the number of contracts made for vessels to be built on the "Isherwood" plan during the past two years. The following table, however, is of considerable interest because, in addition to recording the number and deadweight tonnage of "Isherwood" ships contracted for in each year from 1907 to 1922, it shows to some extent the general activities of the shipbuilding industry during that period of which the "Isherwood" System has taken no small part.

Year	Number of ships built under construction and on order	Deadweight Carrying Capacity
Sept., 1907, to Dec., 1908....	6	31,609
1909	30	181,384
1910	40	271,760
1911	64	474,043
1912	100	818,553
1913	30	215,686
1914	41	358,288
1915	157	1,196,899
1916	152	1,117,779
1917	180	1,666,150
1918	250	2,375,550
1919	210	1,887,000
1920	135	1,367,700
1921	23	70,000
1922	13	69,490
Total.....	1,431	12,101,891

FROM HAMBURG TO PERSIA BY WATER.—During the latter part of July, 1922, the Hamburg Shipping Company, August Bolten, dispatched a specially constructed steamer of 200 gross tons from Hamburg for Enseli, Persia, in order to ascertain the practicability of establishing a regular freight service between Germany and the Near East via the Russian waterways. The vessel sailed through Russian rivers, canals and lakes into the Caspian Sea loaded with a cargo of miscellaneous merchandise and is to remain at Enseli until ice conditions on the Russian waterways permit it to return to Hamburg with a cargo of native merchandise. In view of the apparent success of this expedition the shipping company is planning to extend its services and has placed orders for several ships of a type suited to this route.

Japanese Battle Destroyer No. 16 Launched at Fushinagata Shipyard, Osaka, Japan

Stresses on Vessels of the Great Lakes Due to Waves*

By Professor Herbert C. Sadler† and Professor A. Lindblad††

When the Committee on Bulkheads and Freeboard met to consider the various problems upon which it was to report, the question of the possibility of including vessels on the Great Lakes in the assignment of freeboard arose. As little or no systematic investigation into the strength of this type of vessel had been made, it became necessary to make several strength calculations for the conditions met with in this region. As information of this character may prove of value in other fields, it was thought advisable to have the same in the permanent records of our society. The results of the principal parts of these investigations are submitted herewith.

IN considering the assignment of freeboard to vessels on the Great Lakes, it became necessary to find out what lengths and heights of waves might be expected. Little or no data upon this subject existed, so a series of instructions was issued to captains of vessels in order that they might observe and report upon the waves encountered. Although all possible care was taken on the part of the observers, there was still a chance of error. On the whole, however, the data obtained were sufficiently reliable for the purpose in hand.

A few of the general conclusions are as follows:

1. As a rule, waves over 250 feet in length are rarely encountered. In one case, a report was made of waves in the neighborhood of 350 to 400 feet after a severe storm on Lake Superior, but although the height was not observed it was evidently not of the usual magnitude, judging from other comments on the behavior of the ship.

2. The heights of the waves appear to be somewhat larger in proportion to their lengths than the usual ratio of 1:20, and probably vary between this figure and 1:15. The actual heights did not appear to exceed 20 feet as a maximum.

The following waves were therefore used in the calculations: (a) 325 feet by 20 feet; (b) 300 feet by 20 feet; (c) 250 feet by 16.7 feet and two special cases 325 feet by 15 feet and 350 feet by 20 feet, in order to obtain some intermediate data. As these waves are considerably shorter than the usual run of vessels on the Lakes today, it was necessary to perform two sets of calculations, one with the crest and one with the hollow at the bow.

Three types of vessels were chosen of the following dimensions: (a) 420 feet by 52 feet by 28 feet; (b) 504 feet by 56 feet by 30 feet; (c) 590 feet by 64 feet by 33 feet.

The wave profiles and corresponding positions of maximum bending moment are shown in Fig.

1 for all of the above cases, and the detailed shearing force and bending moment curves in the following Figs. 2 to 4.

As these vessels tend to sag when uniformly loaded, it is customary to put some additional cargo in the forward and after ends. This method of loading has been assumed as the proper one, although calculations were also made for uniform loading.

It will be noticed that both the magnitude and position

of the maximum bending moment depend upon whether the crest or hollow is assumed at the bow, and also that it depends upon the wave dimensions. If the effect of varying heights of waves of the same length is desired, it was found

Fig. 1.—Wave Profiles

that, for moderate changes, the bending moment varies as the square root of the height.

The results have been summarized in Figs. 5 and 6 in the form of bending moment factors.

These charts are reproduced on page 107.

STRESSES

While the foregoing may be considered as general data with regard to bending moments on vessels, it may be of interest to add the special application in the determination of the strength of lake vessels.

If we take the form proposed by the British Committee

*Paper read at annual meeting of Society of Naval Architects and Marine Engineers, New York, November 8, 1922.

†Professor of Naval Architecture, University of Michigan, Ann Arbor, Mich.

†† Assistant professor of naval architecture, University of Michigan.

Fig. 2.—Vessel 420 Feet by 52 Feet by 28 Feet, Displacement 9,735 Tons at 19-Foot Draft

Fig. 3.—Vessel 504 Feet by 56 Feet by 30 feet, Displacement 13,025 Tons at 19-Foot Draft

Fig. 4.—Vessel 590 Feet by 64 Feet by 33 Feet, Displacement 17,225 Tons at 19-Foot Draft

Freeboard, as representing the strength, viz., $\frac{I}{y} = f. d. B.$,

the following may be developed:

If s = stress, BM = bending moment, Δ = displacement, C = bending moment factor, and C_b = block coefficient:

$$\frac{I}{y} \times s = BM = \frac{\Delta \times L}{C},$$

$$f. d. B. \times s = \frac{L. D. d. \times C_b}{35} \times \frac{L}{C};$$

Fig. 5.—Bending Moment Factors

Fig. 6.—Bending Moment Factors and Corresponding Fiber Stresses

Fig. 7.—Standard of Strength

Definitions: $\frac{I}{Y} = f \times d \times B$, where I = longitudinal modulus of resistance; f = longitudinal strength factor, d = draft of vessel, B = breadth of vessel; $f = \frac{C_B}{C_{UB} \times C} \times L^{5/8}$, where C_B = block coefficient, C_{UB} = cubic feet of water per ton (35 for salt and 36 for fresh water), C = bending moment factor = $\frac{\text{displacement} \times \text{length}}{\text{bending moment}}$, L = length of vessel; $f = 0.000573 L^{5/8}$, for salt water, if $C_B = 0.78$ and $C = 39$; $f = \frac{0.0239 L^{5/8}}{C}$ for fresh water, if $C_B = 0.86$.

and if we assume $s = \sqrt[3]{L}$,

$$f = \frac{C_B}{35 C} \times L^{5/8} \text{ for salt water}$$

$$= \frac{C_B}{36 C} \times L^{5/8} \text{ for fresh water.}$$

The proposed values of f are shown on Fig. 7. It is obvious that if the waves on the Lakes do not exceed a certain definite length, the value of f should show a falling off

after this length is reached. This is indicated on the curves, and it is interesting to note that numbers of the present vessels, especially the larger ones, show an excess of the above values; or, in other words, from a strength point of view, they could be loaded deeper than the present depth of water available allows.

In conclusion, and in light of the above investigations, it appears that the lake freighters of today are, for their service, as strong as, if not stronger than, similar ocean-going types, and the statement that these vessels are weaker is not borne out by theoretical investigation or practical operation.

Scout Cruiser Omaha, the Highest-Powered Vessel Flying the American Flag. She Is Propelled by 90,000-Horsepower Westinghouse Turbines and Has a Maximum Speed of 35 Knots

Trial Run of Navy's Highest Powered Cruiser

**Thirty-Five Knot Vessel of Only 7,500 Tons Displacement is
Propelled by Westinghouse Turbines of 90,000 Horsepower**

THE United States Navy Trial Board convened on January 30 at Tacoma, Wash., to supervise the preliminary acceptance trials of the scout cruiser *Omaha*, the highest powered vessel ever built for the United States Navy.

The *Omaha* was built at the plant of the Todd Shipyards Corporation and is the first of ten vessels of her type to be ready for her tests. The trial run was over the Vashon Island course in Puget Sound and lasted over a period of six hours.

These new cruisers are comparatively a new type, at least as regards steaming radius and high speed. The most noticeable features of the designs as compared with contemporary navies are their high speed of 35 knots, their displacement of 7,500 tons and their batteries of twelve 6-inch guns. They are practically exaggerated destroyers, for with a beam of 55 feet and a mean draft of 13 feet 6 inches, they

are 556 feet in length overall, giving a ratio of beam to length of one to ten.

A remarkable feature of the *Omaha* is the enormous power of the four Westinghouse turbines that propel her. When

Sections Through Engine Room

operating at full capacity, these engines will develop a total of 90,000 horsepower. Never before, on land or sea, has so large an amount of power been installed in so small a

Diagram of the Omaha's Propelling Equipment, Showing the Compact Arrangement of Her High-Powered Turbines

space. The turbines of the *Majestic*, the largest steamship in the world, develop 100,000 horsepower, but the *Majestic* is nine times larger than the *Omaha*; while the *Olympic*, which is seven times larger than the scout cruiser, is propelled by engines of only 60,000 horsepower.

However, the *Omaha* needs 90,000 horsepower only when she is tearing through the water at the express-train rate of 35 knots, or 42 miles an hour. For ordinary cruising speeds of from 12 to 15 knots, a few thousand horsepower is amply sufficient. In order to avoid operating her big engines at so small a fraction of their rated capacity, four small cruising turbines are provided. These cruising turbines can be coupled to the propellers when desired and drive the ship at the low speeds with excellent steam economy.

An interesting novelty, at least in the United States Navy, is the adoption for the first time of the tripod mast, at the head of which is located a closed director-fire position, from which the fire from the battery of twelve 6-inch guns will be controlled. A second battery will consist of two 3-inch fifty calibre air-craft guns and two three pounder saluting guns. The vessels will carry two 21-inch twin torpedo tubes which will be located on either beam on the main deck between the aftermost funnel and the main mast.

J. S. Milne, chief engineer of the Todd Shipyards Corporation, who witnessed the trial run, said that no date has yet been set for the trials of the *Milwaukee* and *Cincinnati*, the two other scout cruisers built at the Todd yard.

A New Type of Multi-Stage Centrifugal Pump

WHERE pumps driven by motors of slow or moderate speeds must deliver water at pressures higher than are desirable or practicable for a single-stage pump, instead of using a single-suction multi-staged pump, two separate single-stage pumps are sometimes connected in series, so that one discharges into the suction of the other. In medium and smaller sizes, the use of two independent pumps in series becomes somewhat more cumbersome, and a multi-stage pump is more often used. The length of shaft permissible in a multi-stage pump is limited because of the critical speed, and if many stages are employed, the designer no longer has a free hand in providing water passages of the shape and size conducive to the highest efficiency. Consequently, where more than three stages are required, the single suction impeller, which occupies less space on the shaft than does the double suction impeller, and thus permits the use of a shorter shaft, is used.

However, it is not possible to obtain as high efficiencies with a commercial multi-stage single-suction pump as would be possible in a single stage pump with double suction impellers, not only because of the less favorable limitations imposed on the impeller, but also because there is not sufficient space for an efficient volute diffuser and suitable return passages leading from the diffuser to the eye of the succeeding impeller. The De Laval Steam Turbine Company therefore developed a new type of multi-stage pump, known as a "series" pump, in which the advantages of the double suction impeller are retained. This is made possible by the use of a specially formed casing which provides individual volutes for each impeller, with ample interconnecting passages within the casing itself.

The double suction impeller gives perfect hydraulic balance and two of the stuffing boxes which would be required if two separate casings were employed are eliminated, together with their friction. As compared with a single suction impeller, the double suction impeller has a smaller suction eye, which permits of making the impeller itself smaller in diameter, and hence the pump can be built to operate at a higher speed for a given head and capacity, or for the same

speed, head and capacity, a higher efficiency is obtained. Besides giving the highest efficiency, the volute type diffuser is superior to diffusion vanes, in that it is not subject to clogging or rapid wear, and it also gives a broader efficiency curve, that is, a higher average efficiency over a wide range of delivery.

The pump casing is made in two parts, divided on a horizontal plane passing through the centerline of the shaft, the suction and discharge openings being in the lower part, so that they are not disturbed when the casing cover is lifted. Perfect form and smoothness in the suction and discharge

"Series" Pump with Double Suction Impeller

chambers and the passages connecting the volute of one stage to the suction chamber of the succeeding stage is secured by the use of dry sand molds in casting the casing and the cover.

Leakage from the discharge chamber of each impeller back to the suction chamber of the same impeller is prevented by the use of labyrinth wearing rings. One ring of each pair, known as the case protecting ring, is held in a recess formed in the casing and the casing cover. The other ring, known as the impeller protecting ring, is screwed onto the impeller. The intermeshing grooves of the labyrinth rings present a

Performance of 8-Inch "Series" Pump

long and tortuous path to water leaking from the discharge to the suction chamber, thus greatly reducing leakage while at the same time permitting the use of amply large running clearances. One proof of the effectiveness of this device in preventing leakage is the much longer life of such rings as compared with ordinary flat wearing rings.

The success attained by the series design in improving efficiency is shown by the accompanying chart. The efficiency curve is remarkably flat, that is, a high efficiency is maintained over a wide range of delivery. The advantage in this respect of the single-stage volute pump is now extended to multi-stage pumps of two and three stages.

Stability of Large Ships*

Comparison of G.M. When Ship Enters or Leaves Port and When at Sea

By Sir John H. Biles, K.C.I.E., LL.D., D.Sc.

BEFORE the contracts for some new ships were placed, my advice was asked as to the amount of G.M. (metacentric height) which should be provided for in the light condition. I suggested one foot as a proper amount—not that a less amount would not have been satisfactory, but that experience had shown that during the process of building, additions were likely to be made which would tend to reduce the amount in that condition. Many ships have G.M. in the light condition zero or negative, and are satisfactorily worked.

Obviously, the reliable method of determining the sufficiency of the stability of a ship is to compare the amount which she may have in any condition in which she is likely to be with that which satisfactory ships doing the same kind of work actually have. The recognized method of comparison is to find the G.M. in two conditions—first, the load condition, *i.e.* with coal, stores, passengers, baggage, mails, fresh water and cargo all on board. This corresponds to the state the ship will be in at the beginning of a voyage. The second is the arrival condition, in which coal, stores and fresh water have been nearly all consumed, and such water ballast added as may be found by experience sufficient to enable the ship to be satisfactorily worked.

STABILITY OF A SHIP ON ENTERING OR LEAVING PORT

There is no doubt about the weights of any of the things carried in the ship, except the cargo, which is of such varied character and quality that it is difficult to predict what its weight will be before it comes alongside the ship, and is not easy to determine even when it is there. The recognized method of allowing for cargo weights is to assume that they will be sufficient to load the vessel to her load waterline, and that the center of gravity of the weight will be at the center of gravity of the volume of the compartments of the ship which are devoted to cargo. Upon this assumption the G.M., in both leaving and arriving conditions, can be determined.

The assumption is believed generally to be on the safe side, because it is the general practice, where cargoes are varied in character, to put those of the heavier kind below. It is also frequently found in practice that general cargoes do not fill the cargo spaces, as the parts vary in size so much that it is quite impracticable to fill the spaces up to the beams. The consequence is that the centers of gravity of the cargo in the different compartments are all below the centers of the spaces, and the center of gravity of the ship and cargo is lower than the calculation shows.

Judged by this method, it may be found that a projected ship has as much or more G.M. in the load condition as many other large steamers. In the arriving condition, there may be special conditions in the ports of arrival that make comparison with steamers other than those trading to that port of little value. In some cases the margin of draft is so little that a small inclination of the ship will cause an increase of draft sufficient to cause her to touch the ground at the bilge. To determine the minimum amount of stability, it is necessary to know to what angles similar ships heel on entering the port; what their arriving drafts are; what amount of increase of draft is associated with definite

angles of heel. Such information is not always available, but it is desirable that it should be obtained, and the results interpreted.

It is, however, of interest to compare the two conditions of the ship in which she will have to be in when leaving and arriving in port. They are (1) the fully laden condition when leaving, and (2) the arriving condition after having crossed the ocean. The most unfavorable condition on leaving port, so far as liability to touch the bottom is concerned, is that when the ship is fully laden and is loaded with a cargo which will, in addition to filling the ordinary hold spaces, also fill the portable passenger spaces which may be used for cargo and the reserve bunker with cargo if this is so used. A special case has been taken by way of illustration. In this condition, which we may call (1), the vessel will leave with a G.M. of, say, 2.2 feet. If the ship does not incline, the draft at which she leaves the wharf will be the maximum draft which we need consider, and it may further be noted that in the case chosen a heel of 2 degrees on either side will not increase the draft, but for every additional 1 degree of heel, the draft will be increased by about 6 inches. In the case of the ship arriving at the port, there are two conditions, (2), when the ship arrives with a cargo of about 2,000 tons' weight, and with about 1,000 tons of coal in the bunkers. In this condition, the ship will have a draft of 26 feet 3 inches and a G.M. of 1.8 feet. The other unfavorable condition, (3), is when she arrives with a small quantity of cargo, say about 700 tons, in which case she will have a draft of 24 feet 10 inches and a G.M. of 1.3 feet. Whatever the disturbing cause may be which heels the ship, we can compare the relative effects in these three cases, (1), (2) and (3), and though the information may not be available to say to what angle the ship will heel, it can be seen what are the relative effects upon the increase of draft, due to any assumed disturbing cause.

The following table shows the degrees of inclination and actual drafts for the three conditions, (1), (2) and (3), due to a series of disturbing causes, which in succession will heel the ship in condition (1) to the number of degrees named in the column headed (1). The number of degrees in the columns headed (2) and (3) are the corresponding inclinations that the ships will have for the same disturbing cause.

	(1)	(2)	(3)
Degrees of inclination.....	5.0	6.0	8.4
Draft in feet	30.0	28.3	28.1
Degrees of inclination.....	10.0	12.0	16.8
Draft in feet	32.7	31.5	32.5
Degrees of inclination.....	13.0	15.6	20.0
Draft in feet	34.2	33.3	34.2

From this table it will be seen that in all cases the draft of the ship arriving is not more than that of the ship leaving.

Even in the case where the ship is inclined to the greatest angle, that of the ship leaving port is not less than the others.

It seems unlikely that there can be disturbing causes which could give the ship so much heel, because, if there were, other ships would have been heeled to similar angles, and their drafts would have been increased by about the same amount. If they had been, these vessels would have

*Paper read before the Institution of Naval Architects.

touched the bottom, and the case of the chosen vessel would be no worse than has been the case with them. If they have not touched, then the disturbing cause sufficient to make them touch cannot exist, but in none of the cases does it appear that any advantage would be gained in endeavoring to increase the stability of the ship by adding ballast to the ship or in any other way to avoid touching the bottom. The draft would be increased by the amount of the ballast, and in practically all cases the ship in the arriving condition is safer from touching than the ship in the leaving condition. It does not, therefore, seem to be desirable in the instance chosen to add ballast to the ship on account of the port conditions. Each case may have to be investigated on its merits, but a similar method of investigation should be followed.

The only other question which need be considered in the matter of the stability is that of the heeling of the ship, due to the action of the rudder, when she is in smooth water, and the effect that this heeling will have upon the minds of the passengers. No heeling is likely to be produced which can be dangerous to the ship. But a tender ship arriving in port is very likely to have heeling and oscillations set up under rudder action. There is no doubt that some passengers do not understand why a ship should incline and oscillate in smooth water, but oscillation by itself has no terrors for them, because when at sea in comparatively smooth water and with some small swell on, the vessel will roll for days to degrees of inclination of about an average of 5 degrees, with a maximum of 10 degrees, and the passengers take no notice of it. It seems, therefore, difficult to believe that anyone will be deterred from crossing in a ship on account of the tendency to roll in smooth water, under the rudder action, but the reputation of a ship for stability has to be carefully guarded, and it may be worth while to err on the side of large rather than small G.M. to avoid throwing doubt on a vessel's stability.

If the chosen vessel is in no respect different from other ships of the same class, and there has never been any question as to the safety of such ships at sea, with a G.M. as small as the chosen vessel is likely to have, no water ballast need be added to prevent the vessel from touching when rolling during entering port. It seems, therefore, desirable, before adding water ballast, to very carefully consider the above facts and arguments, and to gain further experience with the ship, before attempting to reduce her draft in the inclined condition by adding water ballast when entering port.

STABILITY OF A SHIP AT SEA

The stability of a ship at sea may be considered from two points of view, first, safety; second, comfort of passengers.

Safety.—By this is meant freedom from liability to capsize. The tendency to return to the upright is the measure of the stability. The causes which move the ship from the upright are (a) the action of the sea, (b) the action of the wind, (c) the shifting of weights inside the ship so that the center of gravity of the whole ship and her loading are not on the middle line and (d) the action of the rudder, about which it is not proposed to say more.

(a) *The Action of the Sea.*—This produces rolling when the sea is not directly ahead. The worst case of rolling is when the period of the waves and the natural period of the rolling of the ship are nearly the same. The natural period of rolling of a ship is what she would have if inclined to some appreciable angle in still water and released from it and allowed to oscillate. The period of the largest Atlantic ocean waves, those of 500 to 600 feet long, is 10 to 11 seconds. The period of a complete oscillation of a large Atlantic liner is about 20 seconds. The period of a ship varies as the beam and inversely as the metacentric height,

so that the broader the ship and the smaller the metacentric height the longer will be the period of roll of the ship and the less will the waves tend to synchronize with and therefore increase the rolling of the ship. Hence, small metacentric height is conducive to small rolling, and so far as the action of the sea alone is concerned, is conducive to safety.

(b) *The Action of the Wind.*—The wind produces the greatest heeling effect when blowing broadside on, and if it has continued for long in that direction will have raised a corresponding sea which will tend to roll the vessel. The wind tends to produce a mean inclination of the ship, and she will tend to oscillate about this mean inclined position. Suppose, for instance, the ship has a mean steady list of 10 degrees due to the wind, and that the action of the sea alone would cause her to roll 10 degrees on each side of a vertical line, she will roll when under the action of the wind to approximately 20 degrees to leeward of her own upright position. As only large waves can make a large ship with a small G.M. roll to large angles by synchronization, it is evident that generally it is better to have a ship with a small metacentric height which will therefore roll little, though that little may be about an inclined axis, than one with a large metacentric height which will roll to great angles about a less inclined axis.

The real question is what smallness of metacentric height is permissible; in other words, to what angle a ship may be allowed to heel under a steady wind pressure in order that her rolling may be reduced, so that the maximum angle to which she inclines shall be the least. Take an example of a ship with, say, $2\frac{1}{2}$ feet of metacentric height which under a wind pressure of, say, 8 pounds per square foot in a heavy gale, force 9 to 10, would incline to a steady angle of $5\frac{1}{2}$ degrees. Such a ship would have a period of oscillation of, say 20 seconds. If this ship's metacentric height be decreased to $1\frac{1}{4}$ feet she would have a steady heel about 11 degrees and her period would be increased to 28 seconds.

If the 20-second period would cause her to roll at least $5\frac{1}{2}$ degrees (the difference between $5\frac{1}{2}$ degrees and 11 degrees) more than the 28-second period ship, her maximum angle of roll to leeward would be more than that of the less stable ship. The motion of the 28-second period ship would be much slower than that of the 20-second period ship. The disadvantage of a greater mean inclination would exist in the less stable ship. Generally, there would be less liability to rolling in the more tender ship, so that the disadvantage of the greater mean inclination might be more than balanced by the advantage of the reduced frequency of rolling and the reduced maximum angle of rolling. It is therefore evident that for a steady wind the reduced stability may, on the whole, in this case, be an advantage. When we consider winds of exceptional force such as forces of 11 and 12, the mean angle of inclination may be undesirable, and it may be desirable to alter course sufficiently to reduce the heeling effect of the wind in the tenderer ship, but this is a very exceptional condition which can be met with safety.

The effects of gusts of wind of great force acting upon a ship when rolling have received some consideration. It has been assumed that it is possible, under very exceptional circumstances, for a ship to roll through 20 degrees on each side of the upright, and that when rolling to windward through 20 degrees she may at the end of a windward roll be struck by a squall of extreme violence which would, by its continued force and by the action of the roll from windward, cause her to roll to a much larger angle to leeward. To estimate the effect of such a combination of circumstances is not easy. The effect of resistance to rolling through large angles is not easy to estimate, but it is known to be very considerable, and if the roll to leeward due to the squall should be 30 to 40 degrees, the total roll would be 50 to 60

degrees, including the 20 degrees from windward. This roll would take place in less than 10 seconds and the velocity of oscillation would be very high. The effect of the wind pressure acting on the surface of a ship is not easy to determine. It can be calculated on an assumption as to the wind pressure on the surface in terms of its area and angle of inclination, but these assumptions may not be accurate. The only thing that seems to be possible is to compare the rolling of ships under such assumed circumstances, and to compare ships on such assumptions, which have for years successfully withstood the storms of the ocean, with any untried ship whose safety it is desirable to estimate.

This has been done in the case of four ships, of which A, B and C have been on service, and D, which is untried. Taking them all in the same conditions as to lading, with light cargo and in a spent and ballasted condition at the end of a voyage, it is possible to make a comparative estimate *disregarding resistance to rolling*, which is very large, but proportionately the same in all the vessels, and assuming the wind pressure to be proportional to the area exposed to the wind (force 10), the results are as follows:

A	32.5 degrees
B	39.5 degrees
C	33.5 degrees
D	37.5 degrees

This result is reached by equating the area of the wind moment curves from 20 degrees to windward to the angle on the curve of stability which includes the same area.

To take account of the resistance to rolling in such ships as these is not very easy. The method of doing so is to assume coefficients of resistance which are based upon experiments made upon ships which have been rolled in smooth water by moving weights across the ship in time with the rolling so as to gradually increase the extreme angle reached. Very few ships have been rolled: and these are nearly all warships. The angle reached has not been very great, nothing like the angles reached at sea when rolling under the action of waves. The laws governing the action of bilge keels in rolling are not fully known on account of the difficulty of carrying out systematic experiments on a large scale to verify any hypotheses. The best that can be done at present is to choose coefficients of resistance from the nearest suitable ship upon which experiments have been made.

H.M.S. *Revenge* was rolled in smooth water by swinging her turrets and running 300 to 400 men across the ship synchronously with the ship. She was rolled without headway and also at speeds of 10 and 12 knots. The bilge keels were 200 feet long and 3 feet deep, tapering at the ends, the actual area for both bilge keels being 1,170 square feet. The center of the keels was 41 feet from the center of gravity of the ship. The dimensions of the ship were: Length 380, breadth 75, draft 27 feet 6 inches; displacement 14,300 tons. The period of a single swing was about 16 seconds, that is, 16 seconds for a double swing. The metacentric height was about 3¾ feet.

The results of the experiments on the *Revenge* may be used for approximating to the resistance to rolling of ships like A, B, C and D, which are ships of about the same order of beam and draft. It will also be possible to compare ships such as these with other vessels of large dimensions which have been running in all kinds of Atlantic weather for many years.

If the resistance to rolling be neglected a comparison between ships having similar elements of resistance such as bilge keels can be made which, while not giving the actual angles to which the ships will roll, will give a means of comparing new ships with those that have successfully withstood the storms of many years. But we may approximate by using the experiments on the *Revenge* to the effect

of resistance and see whether the comparative results are much affected by this resistance. When this is done it must not be assumed that the reduced angles of roll so determined are accurate. They will, as before, only give a comparison of new vessels with old and successfully tried ones. The assumptions which have to be made in order to obtain comparative quantitative results of considerable magnitude (and it is of little use to consider only cases in which the rolling angles are small) must necessarily be only assumptions, and may not represent the actual facts of the case. But they will afford a comparison which for somewhat similar ships ought to enable us to form an opinion on the safety of new ships. On the same assumptions as those already made when resistance to rolling was neglected, *viz.* being struck by a squall, force 10, when at

Fig. 1

20 degrees to windward, the resistance has been approximately calculated with assumed pressures of wind, the angle reached being as follows:

A	25 degrees
C	24½ degrees
D	27½ degrees

B is so near to D that the results have not been worked out. It seems from these results that there need be no apprehensions of the safety of D.

Another instance has been taken which is of comparative value. The vessels E, F, G and H are vessels which have been successfully crossing the Atlantic for from twenty to twenty-five years. They are not dissimilar in dimensions, being 63 feet beam and 28 feet draft, but being much older have less lofty deck erections. The determining factors are the exposed area of side and the maximum righting moment of the curve of stability. In these respects these four vessels are very similar to each other. The case of one, E, has been taken. The inclining effect of the wind pressure is about one-half that of D. Neglecting resistance to rolling it is found that a wind pressure of about 32.7 pounds per square foot would bring E to a condition in which she would reach an angle of roll of about 70 degrees under the same assumptions as to weather roll and leave her with practically no margin of stability, so that a little higher wind pressure would completely overset her. In this condition, D would reach 58 degrees and would have a considerable margin of stability so that she could receive a considerable increase of wind pressure without oversetting. It may therefore be safely assumed that D is at least as safe as E which has for over thirty years successfully continued to run. If we take account of resistance to rolling, the comparison is still better for the ships with bilge keels,

for the four ships E, F, G and H have no bilge keels, and it was demonstrated in the case of the *Revenge* that the resistance to rolling due to bilge keels is such that at comparatively small angles the angle of roll without bilge keels was about three times what it was with bilge keels. In the case of D, if resistance be taken into account, a 32.7 wind pressure will incline her in a squall to $43\frac{1}{2}$ degrees, while E would probably incline to 60 degrees.

It seems, therefore, that there need be no fear for the safety of D.

(c) The third cause which has to be considered is that of shifting the center of gravity of the ship by shifting weights inside her. If the vessel rolls to the large angles, there will be a tendency to shift fuel and cargo. There can be little chance of shifting coal, because in the condition of loading assumed there is but a small quantity of coal left, and this generally will be in the side bunkers which will not permit of much shifting. In other conditions of loading, such as the reserve bunker being partially filled, there is not much chance of coal shifting, as the firemen's passage or some other longitudinal division is in the ship, but the center of gravity of the ship will be lower and the stability greater. Loose water or oil may cause shifting of the center of gravity of the ship, but tanks are usually well divided, and it is usual to empty a tank before beginning to broach another. This should be done as a matter of routine. Where practicable the lee tank should be emptied before the corresponding weather one. The free surface of a tank partially filled tends to set up oscillations which tend to neutralize the effect of inclination. The shifting of cargo is possible, but with ordinary precautions in loading this is not likely to occur. In the case of grain cargoes the trunks leading to the holds will necessarily be well filled to provide feeders for the sinking of the grain. The hatches of the decks below on the trunks should be left off to allow the grain to flow through them as it settles. Special instructions for stowing the grain to avoid the chance of shifting should be systematically given effect to. With these precautions there should be no chance of any appreciable shift of coal or cargo in these vessels.

In the case of heavy rolling due to unusually great wind pressures, it will naturally suggest itself to the master of the vessel to alter course so as to avoid the effects of the abnormal wind pressures. These cases will occur too seldom to appreciably interfere with the successful running of the ship.

The comfort of passengers in rolling is dependent largely on the maximum angle of roll and the period in which this angle is rolled. Those who have been to sea in quick rolling ships, especially if the ships are rolling through large angles, are familiar with the great acceleration which their bodies experience, especially on the top decks far distant from the center of motion. In clear transverse spaces in broad ships the effect of this acceleration is to cause them to find difficulty in holding on to some fixed part of the ship, and if they do not happen to have something to hold on to they will find the operation of being stopped fraught with risk of knocks and possibly bruises. Hence, it is desirable to provide long periods and small angles of roll for the comfort of the passengers.

The question of the relation between the effect of the wind pressure on modern high-sided ships and the meta-centric height is one deserving of the most careful consideration. The curves shown on Fig. 1 give the angles of heel of the ships A, B, C, D, under wind pressures acting steadily or in squalls. The angles of heel are given in the cases when resistance is and is not taken into account.

No attempt has been made to determine the angles of roll due to the action of the sea. This subject is best treated experimentally. To those interested a summary of the general question of rolling given in my Presidential Address

to the Engineering Section of the British Association in 1911 (see *Transactions* of Section C, British Association Meeting at Portsmouth, 1911) may be usefully consulted.

Fiber Flooring for Ship Decks

A NEW type leather and asphalt composition flooring for ship, industrial and office service is being marketed by the James A. Coffey Engineering Corporation, New York. The flooring is made from strips of scrap leather impregnated and bonded in asphalt by a large shoe manufacturing concern as a by-product. It is laid in

Fiber Flooring Is Laid in Asphalt in Sheets 16 by 28 Inches

sheets, 16 inches by 28 inches, and weighs less than four pounds per square foot.

This flooring can be laid over any surface and is ready for use as soon as put down. It can be used as a finished flooring or decking or as an under flooring or decking on ships where it is bonded to the deck and stops the corrosion of steel. Composition, linoleum, rubber and cork tile can be laid over the flooring. The combination of leather and asphalt gives a resilient, noiseless and slip proof surface.

Service tests have been carried out on this flooring over

An Oxy-Acetylene Flame of 6,000 Degrees F. Merely Scorches Fiber Flooring to a Depth of $\frac{1}{4}$ Inch

a period of three years during which time it has been subjected to heavy traffic, heat tests, foot wear and other methods of use to determine its wearing qualities. In the course of the tests, samples of this flooring were exposed for two minutes to the flame of an oxy-acetylene torch and even under the resulting temperature of 6,000 degrees F. were charred only to a depth of $\frac{1}{4}$ inch without flaming. It was also laid in drying rooms where it was exposed to a constant heat of 300 degrees F. without deterioration.

The special features claimed for the flooring are that it is a non-conductor of heat, will not expand or contract, curl or lift, is water and slip proof, sanitary and has long life.

Proportions and Block Coefficients of Merchant Ships*

Increased Beam an Advantage, If Depth and Draft Are Increased
—Economic Proportions Dependent on Depth of Harbors

By W. J. Lovett

LOYD'S REGISTER for 1921-22 contains particulars of about 28,500 steamers, and their analysis on a speed basis is given in Table I.

TABLE I

Speed	Not Exceeding 13 Knots	Over 13 and Under 16 Knots	16 Knots and Under 19	19 Knots and Under 22	22 Knots and Over
Number of vessels....	27,220	737	361	77	34

From these figures it may be assumed that about 3 percent of the merchant steamers of the world are engaged primarily in the passenger trade and the remaining 97 percent are cargo carriers.

An individual analysis has been made for about 700 vessels of 15 knots' speed and over. The dimensions of each were proportioned to a common length of 400 feet, and the comparative mean breadths at varying speeds are shown in Table II, omitting such special vessels as American river steamers. The analysis is given for two groups, viz., vessels of less length than 400 feet and vessels exceeding 400 feet in length.

TABLE II

Mean Proportionate Breadths for Length of 400 Ft.

Length	15-17 Knots Ft.	17-19 Knots Ft.	19-21 Knots Ft.	21 Knots and Over Ft.
Vessels under 400 ft.....	51.4	50.2	49.4	48.5
Vessels over 400 ft.....	48.0	47.0	46.5	44.5

It will be noted that there is a gradual reduction of beam as the speeds increase, and that the small steamers have adopted, or been forced to adopt, greater beam than the large steamers, and this increase becomes more marked when

V

the vessels are considered on a $\frac{V}{\sqrt{L}}$ basis. The market

for, or the supply of, large steamers of 19 knots or over is limited, as there are only 26 vessels of that speed over 400 feet in length, whereas there are 27 vessels under 300 feet, and 58 between 300 and 400 feet that are capable of this speed; so that the fast steamers of our mercantile navies are preponderatingly of short length. Table III has been prepared to illustrate this feature.

TABLE III

Number of Vessels

Speed	Under 200 Ft. Long	200-300 Ft.	300-400 Ft.	400-500 Ft.	500-600 Ft.	Over 600 Ft.
Above 23 knots.....	0	3	10	0	0	4
21-23 knots.....	0	6	24	0	4	4
19-21 knots.....	0	18	24	3	9	2
18-19 knots.....	1	24	17	8	15	7
17-18 knots.....	3	30	26	25	29	9
16-17 knots.....	4	53	39	38	27	6
15-16 knots.....	9	61	40	78	28	1
Total.....	17	195	180	152	112	33

A comparison is made in Table IV between a summary of Table III and a similar analysis prepared from Lloyd's Register for 1914. This shows that at present there is a shortage of almost 200 steamers of 15 knots' speed and over as compared with the 1914 returns, which means that

the world's existing fleet of fast merchant steamers is 20 percent less in numbers than pre-war standard.

TABLE IV

Speed	Number of Vessels	
	1914-15	1921-22
Above 23 knots.....	23	17
21-23 knots.....	46	38
19-21 knots.....	90	56
18-19 knots.....	101	72
17-18 knots.....	125	122
16-17 knots.....	209	167
15-16 knots.....	284	217
Total.....	878	689

Excess of beam involves excess of power in fast vessels where the wave-making resistance is a dominant feature, but in cargo carriers the resistance is largely frictional, and dimensional proportions may be modified within wide practical limits without detriment to the propulsive efficiency. Existing cargo tonnage has a mean breadth of about 1/10L. plus 11 feet, but the published returns of recently built steamers show that the present practice favors increased beam in proportion to length, as is indicated in the list of some broad vessels given in Table V, which could be considerably extended.

For convenience of analysis the beam of each vessel has been proportioned to a common length of 400 feet.

TABLE V

Name of Vessel	Length Ft.	Beam Ft.	Draft Ft. In.	Beam for 400-ft. Length Ft.
John D. Archbold.....	555	75.0	30 0	54.1
Keystone State.....	518	72.0	30 6	55.6
Amsterdam.....	476	65.7		55.2
Almelo.....	447.5	62.8		56.2
Ohio.....	445	61.2	26 9	55.0
Nagara.....	430	61.3	29 4	57.0
Agwimars.....	429	59.2	25 7	55.2
Brielle.....	402	58.3		58.0
P.L.M. 20.....	400	56.0	25 1	56.0
Burgedijk.....	400	54.0	30 2	54.0
Boren.....	377	54.0	24 2	57.3
Assiont.....	370	51.2	24 0	55.3
Kedoe.....	367	51.5	23 2	56.1
Maplemore.....	365	51.0	23 7	55.9
Saint René.....	351	52.5	24 4	59.8
Digby.....	350	50.0	23 6	57.1
Urd.....	334	48.0	21 3	57.5
Sierra Morena.....	331	48.7	22 0	58.8
Kielehaven.....	327	47.3	20 5	57.8
Victor de Chavarri.....	312	48.0	20 2	61.5
Omana.....	303	46.2	19 3	60.9
Sebastian.....	303	43.0	19 10	56.7

Separating the larger of the above vessels from the smaller ones, then, for a common length of 400 feet,

(1) Vessels 400 feet and upward have mean proportionate beam of 55.6 feet.

(2) Vessels under 400 feet have mean proportionate beam of 57.9 feet.

The *Keystone State*, a vessel of 518 feet length, has a beam of 1/10L. plus 20.2 feet.

The *Victor de Chavarri*, a vessel of 312 feet length, has a beam of 1/10L. plus 16.8 feet, and the *Nagara*, a vessel of 430 feet length, has a beam of 1/10L. plus 18.3 feet.

The depth of water available at a port will determine the maximum permissible draft when entering the port, and, as all vessels entering any port are thus limited in draft, it follows that the proportions of beam to draft will vary considerably. For cargo carriers with erections extending over 60 percent of the length, the assigned freeboard draft is a fairly constant fraction of the depth and is only slightly modified by length, sheer and block coefficient. Taking the

*Paper read at the sixty-third session of the Institution of Naval Architects.

same block coefficient, same proportions of deck erections, and same sheer ratio, then

draft = 0.83 depth for 350-foot steamer.

= 0.81 depth for 400-foot steamer.

= 0.79 depth for 450-foot steamer.

If the draft of the vessel is limited, the depth for dead-weight cargoes is fixed by the addition of draft and freeboard, but where the draft is not so limited the depth is fixed by the beam, in order to give a stable vessel under ordinary conditions of lading; and as increasing the draft is the cheapest way to obtain deadweight, this vessel will be the best paying for its owner. Stable proportions of depth to breadth will vary with the erections, but assuming 60 percent of the length to be covered by erections, then a stable depth may be taken as 0.63 beam. Dealing only with two dimensions, it will not lessen the cost, if a vessel of ordinary proportions is made shorter and broader, because, although breadth is slightly cheaper to build than length, there must be a reduction in the block coefficient of the shorter and broader vessel. When, however, the adoption of the greater beam can be utilized to increase the depth, and consequently the draft, it does pay an owner to modify the dimensional proportions of his vessel, and the economical grades between the vessel of ordinary and extreme proportions are largely dependent on the permissible load draft.

The limits of present-day practice may be stated as:

Breadth = 1/10 length plus 18 feet

Depth = 0.63 of breadth

Draft = 0.81 of depth (for 400-foot length)

This gives a vessel 400 feet × 58 feet × 36 feet 6 inches and 29 feet 6 inches draft, and this maximum economic limit for hull cost of ratio of beam to draft is 1.97, but it is seldom practicable to have so deep a draft, and the mean proportionate breadth and draft of the vessels in Table IV may be stated on a 400-foot length basis as 57 feet × 25 feet 9 inches, or a ratio of 2.21 and a difference of 3 feet 9 inches in the draft. An owner is therefore prevented from going to the limit of maximum economic proportions until the available depth of water at the various ports is made suitable for the increased load draft.

The determination of the block coefficient is usually a matter of comparison with similar vessels, but the publication of various model experiment results has suggested a manner of arriving at a maximum fullness of form compatible with economy of propelling power, and presuming in all cases a well-established tank form of model. The proceedings of the technical societies in this and other countries contain records of model experiments variously set out, and in most cases made to demonstrate some definite postulate. These available results, when applicable to cargo vessels, have been plotted to Froude's (K) and (C) values, and in

each case a note was taken of the (K) speed value at midway on the first definite steepening of the (C) curve, denoting an increase in resistance ratio. This frequently occurred in 400 to 450-foot vessels at a (C) value of about 0.7, so that it may almost be inferred that cargo vessels of good tank form of model have their maximum speed for economical propulsion at that (K) value where the (C) curve crosses the 0.7 value datum. Many slow-speed forms have been tried in the tank to give smaller (C) values than 0.7 at the designed speed, although in these cases it is probable that the models could have been made fuller and better paying propositions for their owners, but there is undoubtedly a distinct range or latitude of fullness or fineness, and the owner must decide whether it pays him better to have a fine model and low engine power or to have a full model and high engine power.

The block coefficients in Table VI will enable a form to be designed suitable for the speed intended, but of course a still fuller coefficient might be employed at the expenditure of an excess of power and fuel consumption, and vice versa. These block coefficients are intended to be applied to vessels having midship coefficients within the limits of 0.96 to 0.99, and lengths within the limits of 350 feet to 550 feet.

The results of detailed comparative calculations for various vessels are given in Tables VII, VIII and IX. In each table Type A is a vessel of ordinary proportions having a beam of 1/10L. plus 12 feet, and also of average draft. Type B has same draft but a beam of 1/10L. plus 18 feet. Type C has the extreme beam of 1/10L. plus 18 feet, but has the maximum depth for safe stability and the maximum draft for this depth. The depth in Types A and B have been determined by the addition of the draft and freeboard. In all cases the vessels have plain cargo boat specifications

TABLE VII—6,000 TONS DEADWEIGHT, 10½ KNOTS' SPEED

Item	A	B	C
Length	357 ft.	343 ft.	319 ft.
Breadth	47.7 ft.	52.3 ft.	49.9 ft.
Depth	27.25 ft.	27 ft.	31.42 ft.
Draft	23 ft.	23 ft.	26 ft. 3 in.
Coefficient	0.771	0.733	0.712
Displacement	8,630	8,630	8,500
I. H. P.	1,540	1,620	1,620
Cost of hull	100	100	93

and erections covering 60 percent of the length. The comparative indicated horsepower in each case is stated, and the method of arriving at this power is given in the Appendix.

TABLE VIII—9,000 TONS DEADWEIGHT, 11 KNOTS' SPEED

Item	A	B	C
Length	408 ft.	393 ft.	372 ft.
Breadth	52.8 ft.	57.3 ft.	55.2 ft.
Depth	32 ft.	31.75 ft.	34.83 ft.
Draft	26 ft.	26 ft.	28 ft. 7 in.
Coefficient	0.782	0.75	0.737
Displacement	12,530	12,530	12,360
I. H. P.	2,400	2,370	2,360
Cost of hull	100	100	93

The hull cost, being chiefly dependent on the weight of steel, is comparatively shown as a percentage in all cases, and the basis figure of 100 is given to Type A vessels of ordinary proportions and average drafts.

where A, B, C, D are values given in the following tables A, B, C, D.

Δ = displacement in tons,
V = speed in knots,
L = length in feet.

TABLE IX—12,000 TONS DEADWEIGHT, 11½ KNOTS' SPEED

Item	A	B	C
Length	460 ft.	443 ft.	423 ft.
Breadth	58 ft.	62.3 ft.	60.3 ft.
Depth	35.25 ft.	34.83 ft.	38 ft.
Draft	28 ft.	28 ft.	30 ft. 4 in.
Coefficient	0.791	0.765	0.754
Displacement	16,900	16,900	16,660
H. P.	3,300	3,270	3,250
Cost of hull	100	100	94

CONCLUSIONS

V

In vessels of $\frac{V}{\sqrt{L}}$ up to about 0.65, and trading generally

in smooth water:

- (1) It is an advantage to increase beam, if depth and draft can also be increased.
- (2) It is no advantage to shorten and broaden a vessel, if the draft is not increased.
- (3) It is no disadvantage to increase beam, if necessary for stability.
- (4) Increased beam does not involve reduced speed nor increased power nor increased cost, if displacement is unchanged.
- (5) A minimum depth of channel of 32 feet should be provided at all important seaports.

Appendix

In estimating the comparative horsepowers for the vessels considered it was necessary that some simple tables should be available which would take account of the various dimensions, proportions and speeds involved. After examination, it was decided to try to extend and project the curves given in Taylor's *Speed and Power of Ships* so that they might be used for the assumed cargo vessels. This involved a series of cross curves and an alteration in the method of setting out; but the result is a direct discernment of comparative indicated horsepower for widely varying vessels, and the tables are included here in the belief that they may be of assistance to designers when comparative horsepowers are required. In their application to several known vessels of good form the horsepowers obtained from the tables have closely approximated those installed in the vessels. The formulæ are:

- (1) Wetted surface = $B\sqrt{\Delta L}$.
- (2) Frictional resistance in pounds = $A B C \Delta$.
- (3) Skin horsepower = Frictional resistance $\times V \times 0.0030707$.
- (4) Residuary resistance in pounds = $D \Delta$.
- (5) Residuary horsepower = Residuary resistance $\times V \times 0.0030707$.
- (6) Indicated horsepower = 2 (skin horsepower + residuary horsepower).

Oil Burner for Scotch Boilers

THE Babcock and Wilcox Company, New York, has adapted its latest type mechanical oil burner, the "San Diego," designed for use on Babcock and Wilcox watertube boilers, for service in the furnaces of Scotch marine boilers.

This burner is built according to the same general design as all of the various types of burners produced by the Babcock and Wilcox Company. Its size and proportions, however, are made to conform to Scotch boiler burner conditions. The "San Diego" burner is hinged to the front plate of the furnace and the simple operation of breaking a single pipe

joint and dropping a latch enables the operator to swing out the entire burner and register whenever desired, thus providing free access to the furnace.

Several installations of this burner have already been made on Scotch boilers. The operating results reported indicate

"San Diego" Oil Burner Arranged for Installation on Scotch Boiler

high efficiency, flexibility and ease of operation. On certain installations where "San Diego" burners have replaced other equipment fuel savings as high as 15 percent have been claimed, the oil burning without smoke and with low stack temperature.

Special Type Multiple Drill for Plates

THE accompanying illustration shows a special multiple drilling machine recently built by the Niles-Bement-Pond Company, 111 Broadway, New York, for the drilling, counterboring and tapping of steel plates.

The machine is made up of two double-webbed steel plate girders supported 8 feet 10 inches above the floor by cast-

iron housings placed 44 feet apart. A carriage on wheels, suspended as shown, is arranged to travel the length of the girders, and carries a cross-rail having 13 adjustable drill heads. The machine is mounted on wheels and travels on tracks on the shop floor, being driven by means of a 10 horsepower motor.

The spindles are driven by a 50 horsepower direct current motor mounted on the carriage. Spindle speeds from 120 to 360 revolutions per minute for drilling are provided and, by means of suitable gearing, speeds from 35 to 105 revolutions per minute for tapping. The spindles are 2 inches in diameter at the driving point and have No. 5 Morse sockets. They have a vertical adjustment of 13 inches. The center distances between consecutive spindles are 8 inches minimum, the maximum distance between the outside spindles being 12 feet 8 inches. Suitable spindle feeds are provided and each spindle has an independent feed clutch to permit disengaging one or more of the drills while the others are in operation.

The cross rail in which the 13 drill heads are mounted is pivoted on the carriage which permits swiveling a full revolution, a feature intended to enable the drilling of holes along the edges of plates, in any direction. A constant-speed reversible motor is provided for revolving the cross rail on the carriage and traveling the carriage on the girders, hand movement by ratchet being also provided for the cross rail and carriage.

Graduated scales for setting the drill heads are included and also adequate clamping facilities for the carriage and cross rail. All controls are placed in a position convenient for the operator.

J. T. EASON and F. F. Drysdale, who were formerly with the Supply and Sales Division of the Shipping Board and in charge of the immense stocks of shipbuilding equipment at Hog Island, have organized the Standard Steam Winch & Hoist Company, Perry Building, Philadelphia, Pa., and 100 Broadway, N. Y., which will deal in deck equipment.

Niles-Bement-Pond Machine for Drilling, Counterboring and Tapping Steel Plates

Long-Lived Burner Ring Refractory

IN the furnaces of oil-burning vessels trouble often develops at the burner ring. The flame here is so hot that it finds the cracks between laid-up fire brick. As a result, the bricks crack, crumble and, finally, drop out altogether. The boiler must then be taken off the line while furnace repairs are being made.

This trouble can be obviated, it is claimed, by the use of Plibrico furnace lining which is a refractory, plastic furnace lining that is applied in unbaked form by anyone who can

Plibrico Furnace Lining Applied to Burner Rings

use a mallet and trowel. When heat is applied it is vitrified and baked, to form a rock-like, airtight and gastight lining that is resistant to temperatures to 3,100 degrees F. The Jointless Fire Brick Company, 1130-1150 Clay Street, Chicago, Ill., manufacturers of Plibrico, say that when used in connection with burner rings on private and government owned ships, it has outlasted laid up fire brick two to four times.

Watertight Metallic Joint Features French Port Light

IN the new 75-S port light produced by the Sté. Anonyme des Ateliers et Chantiers de La Loire, Nantes, France, the principal feature is the elimination of rubber or metallic packing between the fixed frame and glass holder or dead light and holder in providing a watertight joint. The pressure on the joint is automatically limited to the exact point of watertightness. The basic principle of the port light is that of a cock plug working in its socket. The actuating mechanism of the device is similar to the breach of a field gun in a somewhat simplified form.

Watertight Port Light in Open Position

The 75-S port light may be supplied with an inside dead light fitted with a metallic joint or a non-watertight outside dead light or with both. The port light may be mounted so as to open either on the right or the

left side. A safety device is also provided to prevent the inopportune opening of the port light.

British Lifeboat Equipped with System of Manual Propulsion

A HAND propelling gear for lifeboats has been developed by I. R. Fleming and Company, Liverpool, England, which consists of a series of vertical levers connected at the lower ends to a fore-and-aft rod at either side of the boat under the thwarts. The fore-and-aft rods are in turn connected at the after end to connecting rods attached to crank disks fitted to a thwartship shaft; on this shaft, which is placed in the stern sheets, is a wheel geared to the propeller shaft. In connection with the thwartship shaft is a reversing gear. The boat is propelled by the passengers or members of the crew who move the vertical levers backwards and forwards thus setting the cranks in motion and thus the propeller shaft. The entire mechanism is encased but is readily accessible for inspection.

The Board of Trade has approved this type of propelling gear and when installed in a boat requires only 50 percent of the number of oars in the equipment.

High Power Marine Signals for Motor Craft

AN audible air-driven marine signal for yachts, cruisers, fishing vessels, motorships and the like is being produced by the American Strombos Company, Inc., Philadelphia, Pa. In the Strombos signal the production of sound is unlike that of any other device or instrument. The sound is produced by the emission through the agency of a specially designed air chamber and the valve action of the diaphragm of sharp individual blasts of air which, occurring with great frequency, set in longitudinal vibration the column of air in the projector; the resulting tone is of great power and penetrating quality.

The signal may be mounted in a horizontal or vertical position and connected to an existing air supply or to a thermo compressor system supplied by the company, which is fitted to the priming cup of one of the engine cylinders and compresses air in a steel reservoir. About 15 pounds air pressure is required to operate the horn but it will work on pressures up to 100 pounds.

The Strombos signal is operated by a lever or valve at the point of installation or by a remote electric push button controlling an electric valve.

Strombos Triplex Type Signal Installed on Motorship William Penn

Questions and Answers Relating to Naval Architecture and Marine Engineering

Conducted by James L. Bates, Naval Architect, and W. B. Newton, Marine Engineer

This department is maintained for the purpose of answering all questions relating to ships and their machinery. All inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

Rule for Estimating Amount of Fuel Oil in Double Bottom Tanks

Q. (1179).—Please give me a rule for estimating the amount of fuel oil in double bottom tanks according to the drag of the ship when you know the amount if ship had no drag. R. J. F.

A. (1179).—Let M be the fore and aft moment about the transverse axis through the sounding tube of the horizontal section of the tank.

Let L be the length between the draft gages or draft marks, whichever are used, for determining the trim of the vessel.

If M and L are expressed in foot units, then the following formula will give the increase or decrease in gallons due to one foot change in trim:

$$\frac{M}{L} \times 7.48$$

In using this formula it is customary to neglect the volume of the structure in the tank, as the error will be inappreciable considering the entire contents. On the above basis a curve is plotted for each tank showing the increase or decrease in capacity due to one foot change of trim of the vessel for the depth of oil read from the sounding tube. For the ordinary inner bottom tank this formula will give a constant correction for usual trims for varying depths of oil except as the tank becomes nearly full or nearly empty when the horizontal section of the tank (referred to above) cannot be used without modification in obtaining M .

How to Calculate Tank Capacities

Q. (1184).—Please inform me as to the best method of ascertaining the capacities of tanks, water or oil, on shipboard.

A. (1184).—The method at present followed by the United States Navy Department is to calculate tank capacities. The calculations are based upon the final plans of the vessels and may be made either by means of the usual rules of integration or by the aid of an integrator. These calculations are so worked out that the results may be plotted as capacity curves showing gallons and tons for feet depth of liquid. Allowance is made for obstructions.

Formerly tanks were calibrated by means of fresh water and standardized measuring tanks fitted with supply and outlet pipes with gate valves and outlets for hose. Every precaution was taken to avoid leaks, air pockets, sharp turns in leads, etc., to insure the tanks being completely filled and to allow for the effect of temperature variation. The results obtained were recorded in the form of curves as above described.

When there are a large number of tanks in a ship, as in the case of a modern capital ship, it is much less expensive

and sufficiently accurate to calculate capacities as in the method first described.

Shrinking Cast Iron Couplings on Steel Shafts

Q. (1185).—Please give me all the information you can in reference to shrinking cast iron couplings on steel shafts. How much larger should the shaft be than the bore of the coupling? Will the same difference apply to large and small shafts? What amount of pressure will be required to draw the coupling, if properly shrunk on shafts of various sizes? What is a good rule for determining the sizes of keys to use? How would you secure a cast iron coupling on a bronze tail shaft?—Engineer.

A. (1185).—The allowance for shrinkage fits varies with the shape, distribution and thickness of the metal around the hole in the part to be shrunk on. This allowance is often the same as for forced fits. The choice as to whether a shrunk or forced fit should be used depends many times upon the size of the parts and the difficulty in handling them.

The following information is taken from Mark's Mechanical Engineers Handbook, page 687, from which the permissible allowances may be determined:

Maximum fibre stress in the hub (pounds per square inch) = $10,000 Kd$, where d = allowance in inches per inch of diameter of hole, m = thickness of hub $\div$ diameter of bore and K = constant having the following values:

	For $m = 0.0$	0.1	0.2	0.3	0.4	0.5	1.0	1.5	2	∞
K (steel hub)	2790	2400	2110	1900	1820	1750	1550	1480	1440	1390
K (cast iron hub)	1400	1250	1150	1070	1030	1000	917	889	867	846

A good rule for a moderate forced fit such as is usually used for a coupling on its shaft is that the shaft shall be 0.0005 inch per inch of diameter larger than the coupling hole.

This rule applies to all diameters of shaft.

Tests have shown that the amount of pressure required to draw a shrinkage fit is about 3.66 times as great as for a forced fit for the same shaft diameters and same allowances as to fit. The pull necessary to withdraw a forced fit may be calculated from the formula

$$P = \frac{250 \times A \times a}{D^{1.65}}$$

In which A = circumferential area of the shaft within the coupling; a = total allowance in inches; D = diameter of the shaft within the coupling; P = load required in tons to withdraw the shaft regardless as to whether the coupling be of steel or cast iron.

The following rule for proportioning keys may be taken as good practice:

- d = diameter of shaft.
- b = breadth of key = $\frac{3}{4}d + \frac{1}{8}$ inch.
- t = thickness of key = $\frac{1}{2}b$.
- t_1 = depth of key way in hub = $0.3b$.
- t_2 = depth of key way in shaft = $0.2b$.

A cast iron coupling should go on a bronze shaft with a moderate forced fit and be secured by one or more keys, the number depending upon the necessary key length required to keep within safe shearing and crushing stress. The keys should be so designed as to carry the entire turning load, no account being taken of the holding power of the forced fit.

Calculations for Cooling Surface of Condenser

Q. (1192).—What is a good rule for determining the amount of cooling surface (surface condenser) for single, compound and triple expansion engines? How do you figure cooling surface of a surface condenser?

Q. (1192).—There are many things entering into the design of a surface condenser, chief among which are temperature of injection, vacuum desired, velocity of water through tubes and pounds of exhaust steam to be handled per hour, which complicate the problem to a point where a rule of thumb is too rough to be used for design purposes. The statement that a condenser contains a certain number of square feet of cooling surface means very little unless it is properly proportioned as to area through tubes per pass and length of tubes.

In order to explain the method used in proportioning a condenser, values will be assumed and an actual case worked out to fulfil certain given requirements.

W = total pounds of exhaust steam handled per hour = 93,000 (given).

I.H.P. = indicated horsepower of engine = 6200 (given).

S.H.P. = shaft horsepower deduced from I.H.P. = $6200 \times 0.92 = 5703$.

R = pounds of exhaust steam per S.H.P. per hour = $W \div S.H.P. = 93,000 \div 5703 = 16.31$.

H_u = useful B.t.u. per pound of steam per hour = $2545 \div R = 2545 \div 16.31 = 156$.

P = engine steam chest pressure in pounds absolute = 280 (given).

Q = quality of steam corresponding to $P = 99.2$ percent (assumed).

F = latent heat of steam at pressure $P = 817.1$ B.t.u. (from Steam Tables).

h = heat of the liquid corresponding to $P = 386$ B.t.u. (from Steam Tables).

H = heat contents of steam at pressure P and quality

$$Q = \frac{F \times Q}{100} + h = \frac{817.1 \times 99.2}{100} + 386 = 1196 \text{ B.t.u.}$$

H_s = heat contents of steam at vacuum in B.t.u. per pound = $H - H_u = 1196 - 156 = 1040$.

t_o = temperature of injection water = 60° F. (given)

P_s = desired vacuum in inches of mercury = 28 (given)

t_s = temperature corresponding to $P_s = 101^\circ$ F. (from Steam Tables)

t_w = temperature of air pump discharge = 85° F. (assumed)

H_t = heat transferred to cooling water, B. t. u. per pound of steam per hour = $H_s - (t_w - 32) = 1040 - (85 - 32) = 987$.

t_h = temperature head or difference between temperature corresponding to vacuum and temperature of overboard discharge = 20° F. (assumed). This figure would decrease as the temperature of injection increased.

t_i = temperature of overboard discharge = $t_s - t_h = 101^\circ - 20^\circ = 81^\circ$ F.

t_r = temperature rise of cooling water = $t_i - t_o = 81 - 60 = 21^\circ$ F.

L = pounds of cooling water required per pound of steam per hour = $H_t \div t_r = 987 \div 21 = 47$.

L_t = total pounds of cooling water per hour = $W \times L = 93,000 \times 47 = 4,371,000$.

Tubes to be $\frac{5}{8}$ -inch outside diameter and No. 16 B. W. G. thick.

A^1 = area through each tube in square inches = 0.192.

t_m = mean temperature difference between water and steam =

$$t_r \div \log e \frac{t_s - t_o}{t_s - t_i} = 21 \div \log e \frac{101 - 60}{101 - 81} = 29.26$$

S^1 = cooling surface per foot of length of the tube in square feet = 0.1636.

n = number of water passes = 2 (assumed)

V = velocity of cooling water through tubes in feet per second = 6 (assumed). This value varies anywhere from 2 to 7 feet per second depending upon the type of vessel in which the condenser is to be installed, and the duty of the condenser.

K_o = heat transferred per square foot per hour per degree mean temperature difference = 525 B. t. u. This value varies with the velocity of the water through the tubes and the mean temperature difference between the water and steam; and has been derived from performance of condensers in service.

S = total cooling surface in square feet =

$$\frac{W \times H_t}{K_o \times t_m} = \frac{93,000 \times 987}{525 \times 29.26} = 5,975.$$

A = area through each pass in square feet =

$$\frac{L_t}{230,400 \times V} = \frac{4,371,000}{230,400 \times 6} = 3.161.$$

N = total number of tubes =

$$\frac{A \times 144 \times n}{A^1} = \frac{3.161 \times 144 \times 2}{0.192} = 4,740.$$

Z = distance between tube sheets, feet =

$$\frac{S}{N \times S^1} = \frac{5,975}{4,740 \times 0.1636} = 7.70$$

NEW BOOKS

THE SHIPPING TRADES INDEX. Size, $9\frac{1}{2}$ by 12 inches. Pages, 479. New York, 1922: Anglo American Publishing Company.

This directory of the various trades and lines of industry connected with shipping, including shipowners, shipbuilders and repairers, coal exporters, bunkering contractors, exporters and importers, marine insurance companies, etc., has been published annually in England since 1890.

The book is designed to be a complete directory of the shipping interests of the world but so far it can only be said to have achieved that object for Great Britain. This is the first year that a section has been devoted to America and, while considerable progress has been made, those looking for a complete index in this book of firms in this country connected with the shipping industry will be disappointed. A fair idea of the proportion of American firms listed may be obtained by the fact that 407 pages are devoted to Great Britain and only 73 pages to America.

OBITUARY

DR. S. TERANO, president of the Japanese Society of Naval Architects, died at Tokio, Japan, on January 8. Dr. Terano was a professor in the Engineering College of the Imperial University of Tokio and chairman of the Board of Directors of the Imperial Japanese Corporation.

BENJAMIN FRANKLIN CRESSON, JR., chief engineer of the Port of New York Authority, died in Montclair, N. J., on January 25 after an operation for appendicitis. Mr. Cresson was educated at Lehigh University and at the University of Pennsylvania. He was Deputy Commissioner for Docks in New York from 1909 until 1913, in which year he resigned to become engineer for the New Jersey commission investigating pier line extensions and port conditions. From April, 1914, to April, 1915, he was chief engineer of the New Jersey Harbor Commission. In April, 1916, he was appointed an associate member of the Naval Consulting Board. From 1917 to 1921 he was a member of the board of experts on terminal construction for the New York State Barge Canal; in 1918 he was consulting engineer to the War Board, Port of New York; from April, 1921, until his death, he was chief engineer of the Port of New York Authority and chairman of the Technical Advisory Board.

Colonel John O'Neill Awarded Distinguished Service Medal of Congress

JOHN O'NEILL, assistant general superintendent at the International Mercantile Marine Company's Chelsea piers at New York, has received the Distinguished Service Medal of Congress, awarded for services rendered in the debarkation of troops at New York and the port of Brest during and following the war, at which time he was attached to the engineers, having been mustered out with the rank of lieutenant colonel. The presentation was made at 10 a. m., January 20, at the Officers' Club, Pier 60, North River, by Brig. General George H. Harries, O.R.C., under

Colonel John O'Neill Receiving the Distinguished Service Medal of Congress

whom Colonel O'Neill served. Colonel O'Neill has also received the red ribbon of the Legion of Honor of France. He holds several medals for life saving, both at New York and at Boston, where he formerly worked. On several occasions he has jumped overboard in winter to save a drowning man. His first rescue was in 1904, when he saved a man who had fallen into Boston harbor from the White Star liner *Romanic*. In 1907 he led a rescue party into the forecandle of the steamship *Anglican* when the vessel was filled with fumes from burning sulphur, and assisted in the rescue of several men. In March, 1910, he jumped from the steamship *Megantic* at midnight and held up a drowning man 35 minutes in icy water until help came. In February, 1916, he was three quarters of an hour in freezing water steamship *Colonian*. Mr. O'Neill began life as a stevedore at Liverpool, for the Dominion Line. He enlisted in the army in 1917, and after embarkation work at Newport News was

sent overseas in October in the army transport service with the rank of captain. He assisted in the debarkation of 882,000 soldiers in France, and between the armistice and November 23, 1919, helped embark 1,102,000 men for home. He was mustered out December 22, 1919.

PERSONAL MENTION

H. G. SMITH has been appointed vice-president of the Bethlehem Shipbuilding Corporation, Ltd., in charge of sales with offices at 25 Broadway, New York.

ALFRED GILBERT SMITH, president of the New York and Cuba Mail Steamship Company, has received the nomination for president of the American Steamship Owners' Association. Mr. Smith has been actively engaged in ocean shipping all his life. In 1883 he entered the service of James E. Ward and Company, agents of the New York and Cuba Mail Steamship Company, and served through all the departments. In 1907 he was elected vice-president, general manager and a director of the New York and Cuba Mail Steamship Company and was appointed a member of the executive committee of the board of directors in 1916. Three years later he was elected president of the company to succeed Henry R. Mallory. Mr. Smith is a director of the Atlantic, Gulf and West Indies Steamship Lines, the Clyde Steamship Company, the Mallory Steamship Company, the New York and Porto Rico Steamship Company and the International Shipping Corporation.

A. G. Smith

EDWARD T. FISHWICK has been appointed vice-president in charge of sales, and general sales manager of the Worthington Pump & Machinery Corporation, 115 Broadway, New York.

G. T. BRADLEY, formerly traffic manager of the United States Shipping Board Emergency Fleet Corporation at Baltimore, has been transferred to New York as assistant head of the European and Mediterranean Trades Division.

DONALD F. WASHBURN, former assistant head of the European Trades Division in the Washington office of the United States Shipping Board Emergency Fleet Corporation, has been transferred to Baltimore as traffic manager of the Board.

P. SINCLAIR, assistant to the director of finance, United States Shipping Board Emergency Fleet Corporation, has resigned from this position, his resignation to take effect at the close of the present fiscal year. Mr. Sinclair joined the Emergency Fleet Corporation in April, 1922, and has had charge of the comptroller's department since that time.

D. A. BURKE, at present district comptroller of the United States Shipping Board Emergency Fleet Corporation at Philadelphia, will succeed P. Sinclair, assistant to the director of finance of the United States Shipping Board, Washington, D. C., whose resignation has just been announced. Mr. Burke will immediately be associated with Mr. Sinclair in the management of the comptroller's department, assuming complete control when Mr. Sinclair's services with the Board will have been completed at the end of the fiscal year.

Shipbuilding, Reconditioning and Operation

Port Expansion, Passenger and Freight Activities and Other
Notes of Interest in All Branches of the Marine Industry

Year's Activities Under Way

THE autumn of 1924 will see the Clyde Steamship Line equipped with two new ships for New York and Florida service, according to a statement made by H. H. Raymond, who was a guest of honor at a recent session of the Civitan Club in the Seminole Hotel, Jacksonville, Fla. Mr. Raymond, who was called on for a talk, announced that a naval architect is now making the specifications and that those and the plans will be submitted to the company in April of this year, and that these two ships will be ready for the direct from New York to Jacksonville service in the fall of 1924.

The North Atlantic & Western Steamship Company, commonly known as the Nawsco Line, and engaged in coast-wise service between the Atlantic and Pacific Coast ports of the United States, looks forward with confidence to a record-breaking year as far as domestic business in the United States is concerned. The company is gradually putting itself in shape to be able to buy tonnage, presumably from the Emergency Fleet Corporation, with the ultimate purpose of converting such vessels from steam to Diesel propulsion. It is through the medium of internal combustion engines that the company hopes to reduce its operating expenses.

The United States Engineer Office, Galveston, Tex., which at present maintains and operates one seagoing hopper dredge and six hydraulic pipe line dredges, three derrick barges, one steam seagoing tug and about twenty smaller internal combustion drive tugs and launches, with three large barges working by contract, has an unexpended balance available for 1923 of approximately \$2,275,000. For the replacement of wornout pumps the office will probably purchase during the year two 20-inch sand pumps. About \$250,000 per month is being expended mostly for dredging operations.

The Engineer Office, for the First District, New York City, is understood to be considering the possibility of converting one or two dredges from coal to oil burning during this year, while the office at Jacksonville, Fla., is planning to construct three steel barges, each 80 feet by 26 feet by 5 feet for use of the dredge *Mallery*.

Newport News Co. Low Bidder For Four Dump Scows

WITH a price of \$190,000 and a time figure of 45 days, the Newport News Shipbuilding & Dry Dock Company, of Newport News, Va., submitted the lowest tender for the construction and delivery of four steel dump scows complete, at the opening of bids at noon, on January 15, by Colonel Earl I. Brown, Corps of Engineers, U. S. Army, at Philadelphia, Pa.

The boats are to have an overall length of 144 feet, width overall 37 feet, depth of deck to inside 11 feet 8 inches, and are to be of the 7-pocket bottom dump type, each of about 850 cubic yards total capacity. Nine companies bid for the work.

West Palm Beach to Vote on \$250,000 Terminal Issue

THE City of West Palm Beach, Fla., is about to vote on bonds for the purchase and improvements of terminal locks and other accessories and a cross state railroad. The amount of the issue will be \$250,000 and the chances are strong that it will carry. The date of the election is February 13.

Ten Ships Under Order Abroad for the Eastern Steamship Company, of Canada; Also Five Canadian Lakers

TEN vessels are being placed to the order of Mr. A. B. Mackay, according to information received by MARINE ENGINEERING AND SHIPPING AGE, for the Eastern Steamship Company, of Canada, as follows:

Two vessels from J. S. White & Company, East Cowes.

Two vessels from Furness Steamship Company, Haverton Hill.

Two vessels from Napier & Miller, Old Kilpatrick.

Two vessels from Earles Shipbuilding Company, Hull.

One vessel from Cammel Laird & Company, Birkenhead.

One vessel from J. I. Thornycroft & Company, Southampton.

It is understood that the order for these vessels were negotiated for through a firm of shipbrokers, Messrs. Vogt & Maguire, in Liverpool.

This order has been placed by Messrs. H. E. Moss & Company, Liverpool, shipbrokers, who have, it is understood, also placed contracts for two steamers of a similar description with other builders on the North East Coast.

Quarter Million Dollar Contract for Two Tugs Awarded Tebo Plant; Will Be of Steel and Oil Burning

THE Tebo Yacht & Basin Company, of the Todd Shipyards Corporation, has been awarded a contract for the construction of two steel oil burning tugboats for the Standard Transportation Company, 26 Broadway, New York. Deliveries are scheduled for June and July. It is under-

stood that the total cost will be close to \$225,000.

Each vessel will have a length overall of 105 feet 9 inches, breadth molded 24 feet, depth molded 12 feet 9 inches. Propulsion will be by reciprocating engines developing about 800 horsepower.

Two Diesel Lightships Planned

THE construction of two light vessels propelled by Diesel engines and equipped throughout with electrically driven auxiliaries, is the latest project contemplated by the Bureau of Lighthouses, of the Department of Commerce, Washington, D. C.

According to information obtained by MARINE ENGINEERING AND SHIPPING AGE, the desire to build a light vessel capable of remaining on station for one whole year without re-fueling at sea led the Bureau to the consideration of fuel oil burning instead of coal. Its investigations developed the following advantages for fuel oil: (1) less bunker space required; (2) smaller fireroom force; (3) less corrosion to ship in bunkers; (4) more flexible in maintaining low head of steam; with the following disadvantages: (1) bunkers more expensive to build; (2) dangers of leaks due to working of ship in exposed stations necessitating extreme precautions in designing connections and fastening, riveting, calking, etc.; (3) more machinery in boiler room to maintain, necessitating duplicate installation; (4) necessity of educating present personnel to new type of firing.

After consideration, it was decided to build *Light Vessel 105* adapted for oil burning. *Light Vessels 106-110*, later contracted for, were made oil burning based largely on the performance of *Light Vessel 105*. Diesel engines were then considered for this service and after investigation as to flexibility of control and economy in operation and having overcome the disadvantages of carrying fuel oil in bulk, the construction of two new Diesel drive ships, *Light Vessels 111 and 112*, equipped complete with electric auxiliaries, is planned.

Three and a Quarter Millions Required to Meet Vessel Needs of U. S. Lighthouse Service

THE increasing need of additions to the vessels of the Lighthouse Service, involving an expenditure of approximately \$3,260,000 during the next three years, is pointed out in the annual report of G. R. Putnam, Commissioner of Lighthouses, to the Secretary of Commerce. In referring to the light vessel situation, new construction and reconditioning needs, etc., the Commissioner states:

NEED FOR REPLACEMENT

The annual reports for 1919, 1920, and 1921 gave full statements of the urgent need for the construction of additional vessels for the Lighthouse Service to replace those worn out in service, those lost through various casualties, and to meet the considerable growth of the service. The duty of the two types of vessels, tenders for buoy work and supply purposes, and light vessels for floating lighthouses, was explained, as well as the severe usage and hazardous service to which these vessels are exposed.

These conditions have been alleviated for the present with regard to large seagoing tenders by the transfer to this service from the War Department of six large mine-planting vessels.

The need for new light vessels is increasing. There are no vessels in other departments or the Shipping Board available for transfer which are suitable for use as light vessels, due to their special design and construction requirements. To maintain the serviceability of the light vessels, it is necessary to construct an average of two each year. Since 1910, and particularly since the beginning of war conditions, there has been a considerable deficiency in the building of vessels sufficient to keep up this program.

Of the light vessels now in use, 22 are more than 30 years old, and 11 are over 50 years old. Many of the lightships are not in condition to be safely placed on exposed stations. The cost of repairs and overhaul becomes so heavy that it is not economical to keep in commission vessels after they have reached a reasonable limit of usefulness. The effect of continuing the use of these old ves-

sels is often a greatly diminished output of work with the same or greater cost of operation and upkeep. Of more importance than the question of efficient and economical operation, however, is that of safeguarding life. Both lighthouse tenders and lightships are engaged on hazardous duty, and their officers and crews should not be required to serve on vessels which have passed a reasonable limit of usefulness, nor can the Lighthouse Service properly perform its part in the safeguarding of life and property on the navigable waters of this country without necessary vessel equipment.

Congress, by the act of June 5, 1920, after full hearings, authorized a building program for vessels for the Lighthouse Service of \$5,000,000, and an appropriation of \$1,000,000 of this amount was made in the act of March 4, 1921. Under this and previous appropriations the following vessels are now under construction: Light vessels to replace No. 20, Cross Rip, Mass., No. 3, Handkerchief, Mass., No. 11, Scotland, N. J., No. 34, Charleston, S. C., and No. 43, relief, eighth district; tender to replace *Goldenrod*, fourteenth district. On the last contract much lower bids were received than for a number of years, and this appears to be a favorable time for vessel construction. No further vessels can be built, however, under available appropriations. During the fiscal year

Examinations For Draftsmen

THE United States Civil Service Commission announces an open competitive examination for ship draftsmen, Grade A (small boats). Vacancies in the Bureau of Construction and Repair, Navy Department, Washington, D. C., at \$6.80 to \$8.80 per diem, plus bonus. Appointees at annual compensation of \$2,500 or less, whose services are satisfactory, may be allowed the increase granted by Congress of \$20 a month. Applicants should at once apply for Form 1312, stating the title of the examination desired, to the Civil Service Commission, Washington, D. C.; the Secretary of the United States Civil Service Board, Customhouse, Boston, Mass., New York, N. Y., New Orleans, La., and postoffices in the principal cities.

three tenders and four light vessels which had been condemned as unfit for further service were sold, the very small prices obtained indicating their extremely worn-out and unserviceable condition.

From careful estimates and examinations as to the condition and further serviceability of vessels of the Lighthouse Service it is found that, in addition to those provided for by vessels now building, 14 light vessels and 5 tenders should be replaced within the next five years. As it will require from two to three years after appropriation is made before vessels are available for service, funds should be provided now for 8 of these vessels, being those more urgently needed, and first named in the following list:

ADDITIONAL VESSELS FOR WHICH APPROPRIATION IS NOW NECESSARY OR SHOULD BE AVAILABLE WITHIN THE NEXT THREE YEARS.

Light vessel to replace No. 4, relief, second district, second class.....	\$200,000

Outboard Profile of Proposed East River Ferries

Plans and Specifications for Eight Ferries to Cost \$1,475,000 Submitted to Estimate Board

Vessels Are to Be Built of Steel Having a Length of 130 Feet
Driven by Twin Screws—Specifications Provide
for Steam Engines With Alternate Bids
for Diesel Installations

PLANS and specifications for the construction of a total of eight ferryboats for New York City, to be built at a total cost of \$1,475,000, have been submitted by Grover A. Whalen, Commissioner of Plant and Structures, to the Board of Estimate and Apportionment, with a request for the authorization of funds. The commissioner requests five new boats to cost about \$925,000, for the Grand Street-Broadway Municipal Ferry Line and for the Union Ferry Lines, which were taken over by the city on December 17, last, and three boats to cost about \$550,000, for the East 92nd Street-Astoria and Clason Point-College Point Ferry Lines.

For these various East River Lines the commissioner plans an all steel boat, having

a length over guard of 130 feet, beam over guards 52 feet, draft 8 feet 6 inches, driven by screw propellers instead of side wheels, with three gangways for vehicles and two cabins, all on one deck. The boats are planned to be driven by high pressure two-cylinder steam engines, but alternate bids will be received for equipment with either double compound steam engines or Diesel engines, direct connected. In the case of the steam installations, oil will be used for fuel instead of coal, the boats being designed to make a speed of 10 miles an hour instead of 5 or 6.

Commissioner Whalen stated that the boats can be operated much more economically than the present ferries, saving not only in repairs and maintenance but in actual operating costs.

Contract Awarded Hildebrand Yard, Kingston, for Construction of Two More Diesel Towboats

THE contract for the construction of two Diesel towboats for the Transmarine Corporation, of 11 Pine Street, New York City, has been awarded the Hildebrand Shipyard, at Kingston, New York. The boats were designed by R. R. Livingston, naval architect and marine engineer, Rector Street, New York, and are duplicates of three boats recently completed by

the same shipyard and which were also designed by Mr. Livingston. It is understood that the contract will involve approximately \$75,000.

The boats will have an overall length of 63 feet, beam 14 feet, draft 7 feet, the propelling machinery of each boat consisting of a 6-cylinder 180 horsepower Nelsco Diesel engine.

Gasoline Ferry Rebuilding; New Boilers in Mate

THE gasoline ferry boat *Pelican* is undergoing a complete rebuilding at the South side dock of the Jacksonville Ferry and Land Company, with the view of placing the craft on the run now being taken care of by the steam ferry *Duval*. The change will only be temporary, states J. N. Cook, manager of the company, the *Pelican* to run while the *Duval* is having new boilers installed.

The deck of the *Pelican* will be renewed, two new cabins built, and a runway for automobiles enlarged.

Ward Works Low For Constructing Dredge Wautaga

THE Charles Ward Engineering Works, Charleston, W. Va., was low bidder for the construction of a 2-cubic yard steel dipper dredge, to take the place of the dredge *Wautaga*, at the opening of bids by United States Engineer Office, Nashville, Tenn., on January 16. The company's price was \$60,574.

The proposed boat is to have an overall length of 108 feet.

New Bulkhead

COMMISSIONER of Docks, Pier A, foot of Battery Place, North River, Manhattan, received sealed bids at 12 o'clock, noon, on Monday, January 22, for the construction of a concrete bulkhead wall along the Harlem River Driveway, between 165th and 193rd Streets. The contract will cost close to \$200,000.

Marine Construction News of the Month

Ship Contracts—New Ship Concerns and Shipyard Improvements—Terminal Projects—Government Contracts

SHIPS AND SHIPBUILDING

Repair Work, Baltimore, Md.—H. E. Crook Company has been awarded the contract for repair work on the steamer Dallas.

Docked and Overhauled, Mare Island, Cal.—The navy tug Vigilant was taken to the Mare Island Navy Yard for docking and overhauling.

Miscellaneous Repairs, Chester, Pa.—The Shipping Board steamship Chickamauga has been awarded to the Sun Shipbuilding Company for miscellaneous repairs.

Steamship Drydocked, Chester, Pa.—The Shipping Board steamship Bannock was awarded to the Sun Shipyard for drydocking and miscellaneous repairs.

Steamer Purchased, New York.—Steamship Canibas, 9,947 deadweight tons, was bought at auction by the Matson Navigation Company for \$198,100.

General Repairs, Floreffe, Pa.—The steamer Vulcan of the Vesta Coal Company was placed on the marine ways of the company at Floreffe for general repairs.

Japanese to Convert Liners.—All the Nippon Yusen Kaisha liners operating between Yokahama and the Atlantic seaboard of America are to be converted into oil burners.

Collision Damage Repairs, Brooklyn, N. Y.—The Morse Dry Dock & Repair Company was awarded the contract to repair collision damage on the steamship Mexico. Price about \$22,000.

Steamers Sold, New York.—The Shipping Board has sold the ex-Atlantic-Gulf and Pacific steamers Henry S. Grove and Charles H. Cramp to the Argonaut Steamship Corporation of New York.

Tanker Drydocked, New Orleans, La.—The Mexican Petroleum Corporation's tanker Crampton Anderson was placed on the docks of the Jahnke Dry Dock Company for overhauling and repainting.

Contracts Awarded, Philadelphia, Pa.—Cramp Ship and Engine Building Company was awarded the contracts for work on the British tanker Cheyenne and the American schooner Esther K.

Contract Award, New York.—The New York Harbor Dry Dock Company was awarded a contract for repairs to the steamship West Calumb, for which bids were opened on December 21. The price was \$1,278.

Minor Repairs, West Coast.—The Pacific Coast Engineering Works was awarded the contract for replacing the main steam pipe and other minor repairs to the engines of the steamship Bessie Dollar.

Steamer Allocated, New York.—The Shipping Board has allocated to the Cosmopolitan Line the 8,550 deadweight ton steamer Cohasset, for service from New York and Philadelphia to French Atlantic ports.

Repairs and Drydocking, Philadelphia, Pa.—The Pennsylvania State Nautical Schoolship Annapolis has been taken to the League Island Navy Yard for minor repairs and drydocking preparatory to the winter cruise.

Car Float Launched, Camden, N. J.—A car float 340 feet long, built for the Brooklyn Eastern District Terminal Company, was launched at the yards of the New York Shipbuilding Corporation, Camden, N. J.

Repairs, Brooklyn, N. Y.—The Robins plant of the Todd Shipyards Corporation has been awarded the work of repairing the tank steamer Alabama, which recently went aground off the Mexican coast, at a cost of \$77,000.

Steamship Purchased, New York.—The Garland Steamship Line has purchased the steamship West Cavanal, of 8,564 deadweight tons, 410 feet long with a 54-foot beam. Price \$171,000. She will be generally overhauled.

Aero Alarm Contracts.—The Seattle office of the Aero Alarm Company has contracts for the extension of the Aero Alarm System on the steamships President Jackson and President Grant, of the United States Shipping Board.

Repairs to British Steamship, Brooklyn, N. Y.—With a bid of \$66,000, the Morse Drydock and Repair Company has been awarded a contract for repairs to the British steamship Cairndhu, which grounded in the St. Lawrence River.

Schooners Docked, Baltimore, Md.—Schooners Charles G. Gawthrop and W. H. Woodin, purchased by the Maryland Navigation Company from the American Car and Foundry Company, were taken to Baltimore to be fitted out for service.

Steamship Drydocked, Sparrows Point, Md.—Steamer City of Flint, of the Exportation Transportation fleet, was placed on the docks of the Sparrows Point plant of the Bethlehem Shipbuilding Corporation preparatory to loading for Europe.

Two Tugs Sold.—The Shipping Board has sold the 418 gross ton steel ocean type tug Barren Fork to S. A. Guilds, of Charleston, S. C., and the similar type and tonnage tug, Butterfield, to the Newaygo Tug Line, Inc., of Wisconsin Rapids, Wis.

Transport Purchased.—The Robert Dollar Company has purchased the former army transport Dix. This vessel, having served for more than twenty-five years on the Pacific, is expected to be used in the trans-Pacific trade. Price, approximately \$25,000.

Steamer Allocated, Mobile, Ala.—The steamer Westland, of 6,800 deadweight tons, has been allocated by the Shipping Board to the Waterman Steamship Company, of Mobile, Ala., for its Mobile-Liverpool and West Coast United Kingdom ports' service.

Steamers Repaired, San Pedro, Cal.—Steamers El Cicuta, El Abeto and El Cedaro, recently purchased by the Los Angeles Lumber Products Company, were awarded to the Los Angeles Shipbuilding & Dry Dock Corporation yards to be converted to oil burners.

Steamship Purchased, West Coast.—The Alaska Steamship Company has purchased the Shipping Board steamship Delrosa for service between Seattle and Alaskan ports. The vessel can carry 5,000 tons of cargo, is 321 feet long, 46 feet beam and 24.4 feet in depth.

Vessels Drydocked, San Francisco, Cal.—The Bethlehem plant was awarded the following contracts: Asbury Park, drydocked for cleaning and painting; the Yellowstone, cleaning and painting; W. S. Rheem, drydocking; Barge 95, of Standard Oil Company, for survey.

Successful Trials, Pa.—The new passenger and freight steamship Haleakala, built for the Inter-Island Steam Navigation Company of Honolulu by the Sun Shipbuilding Company, Chester, Pa., passed successful trials off the Delaware Capes, exceeding its contract speed of 17½ knots.

New Engines for Coaster, Oakland, Cal.—Two new thirty-five-ton Diesel engines are being installed in the steamer Frank Lynch of the Frank Lynch Lumber Company, of San Diego, by the Crowley shipyard crew at the plant of the Union Construction Company in Oakland.

Contract Awarded, Staten Island, N. Y.—The New York Harbor Dry Dock Company, low bidder with a price of \$38,900, received the contract for alterations and installations on the 353-foot combination passenger and cargo steamer President Arthur, of the United States Shipping Board.

Shipyard Activities, Oakland, Cal.—The Hanlon Shipbuilding and Drydock Company has been awarded the contracts on the following: Lumber carrier Edna Christenson, new tail shaft; steam schooner Necanicum, schooner Resolute and bark Monongahela, general repairs and drydocking.

New Ships Ordered by Canada.—Thirteen steamers, averaging 250 to 300 feet long, have been ordered or are ready to be placed with British shipyards for use on the Great Lakes of Canada and the United States. These boats will be capable of carrying from 90,000 to 100,000 bushels of wheat.

Tankers Drydocked, Galveston, Tex.—The Shipping Board tankers Houma and West Erral were taken to Galveston to be drydocked for overhauling. The tied-up Shipping Board tankers at Orange, Texas, will gradually be withdrawn and brought to Galveston for repairs as the demand for tonnage increases, according to officials.

Sale of Two Lake Type Vessels.—The Shipping Board has sold the lake type steel cargo vessels Lake Gera, of 4,155 deadweight tons and 2,637 gross tons, to the Lone Star Steamship Company, of Galveston, Texas, and the similar type vessel, Lake Pepin, of 2,989 deadweight tons and 1,997 gross tons, to the Hammond Lumber Company, of San Francisco.

Fishing Steamers, Maryland.—A contract has been awarded to M. M. Davis & Son, shipbuilders at Salomons, Calvert County, Md., for the construction of two fishing steamers for fish-products factories at Reedville, Va. One of the vessels is to be 140 feet long, the other 135 feet, the larger of the two to be equipped with two 200-horsepower crude oil engines. Both are to be lighted by electricity.

Vessels Drydocked, West Coast.—The following vessels were reported drydocked: At the Moore Shipbuilding Company, steamers South Coast, Mount Baker, Carolyn Francis and tug Crolone; at the Crowley yards, steamers Admiral Schley, Jephtha, destroyer De Long, subchasers Vaughn and Cygon and barges Crowlet 9 and Napa; at the Bethlehem yard, steamers Vinita, West Jena, Grays Harbor and Acme.

Steamer Reconditioned, San Pedro, Cal.—The Los Angeles Shipbuilding and Dry Dock Corporation was awarded the contract to recondition the steamship Calavai, formerly the United States Army transport Sherman, by the Los Angeles Steamship Company; the work to consist of complete overhauling, entire refitting and refurbishing of all passengers' quarters, and conversion to an oil burner. Estimated cost \$300,000.

Stern Wheel Harbor Boat, Pittsburgh, Pa.—The Marietta Manufacturing Company has received a contract from the Jones & Laughlin Steel Company for the construction of an all-steel stern wheel harbor boat. This boat is to be 64 feet long on deck and 82 feet overall. The boat, which will be engaged in the Pittsburgh-Aliquippa trade after completion, will be of the scow prow type, equipped with a Fairbanks-Morse Diesel oil burning engine of 200-horsepower, with a solid drive shaft.

Steamers Allocated, New York.—The Shipping Board has allocated the 9,789 deadweight ton steamer Waukegan to the Cosmopolitan Shipping Company of New York, for their New York-Philadelphia-French Atlantic service; the steamer Cohasset, 8,500 deadweight tons, to the Black Diamond Steamship Corporation of New York, for their Philadelphia-New York-Antwerp general cargo service, and the steamer Abren, 7,814 deadweight tons, to the Export Steamship Corporation of New York for their New York-Levant general cargo service.

Vessels Awarded for Repairs, New Orleans, La.—The Jahnke Dry Docks, Inc., has been awarded the following contracts: Minor repairs to steamship West Segovia of the Shipping Board, damaged by

fire, repairs consisting principally of replacing a bulged and buckled deck plate, restoring a little woodwork and renewing burned out electrical installations; steamship Blaafjeld, to undergo alterations and repairs; steamship Rajab, for overhauling; and the Tegucigalpa, Vaccaro Brothers Steamship, the barge Chagres and the Mississippi Warrior tow-boat Natchez, for repairs.

SHIPYARDS AND DRYDOCKS

Shipbuilding Plant Sold, Port Wentworth, Ga.—The plant of the Terry Shipbuilding Corporation, at Port Wentworth, has passed into the hands of the Georgia Wool Stock Company and the American Mills International Company, both of Atlanta, at a price of \$506,000.

Shipyards to Be Dismantled, Bristol, Pa.—The yard of the Merchant Shipbuilding Company at Bristol, Pa., is to be discontinued and the ways there dismantled, as a result of concentration of all the shipbuilding activities of the Harriman interests at the single shipyard of William Cramp & Sons' Ship and Engine Building Company, at Philadelphia, according to announcement by R. H. M. Robinson, chairman of the executive committee of the company and president of the Merchant Shipbuilding Company, also a Harriman shipbuilding organization.

Facilities Enlarged, Los Angeles, Cal.—According to announcement by Charles M. Schwab, head of the Bethlehem Steel Corporation, following inspection at Los Angeles Harbor of the Bethlehem Shipyard and Dry Dock Corporation, a larger drydock than the present one now in use and increased shipbuilding facilities will be erected shortly at the Los Angeles yards. Vice-president E. B. Hill, of the Bethlehem concern, who accompanied Schwab on the inspection trip, indicated that the Bethlehem plant there would soon devote greater energy to the manufacturing of Diesel engines.

Crook Company Gets Repair Plant, Baltimore, Md.—The drydocking and repair facilities of the Union Shipbuilding Company have been taken over under a lease by H. E. Crook Company. These additional facilities will be operated in conjunction with the present yard of the Crook Company at Locust Point, Md., and will be used primarily for underwater work, enabling docking of vessels up to 420 feet in length and to handle heavy and light repair work and mechanical installations of every description. A Crandall 10,000 deadweight ton electric railway, along with the rest of the equipment, all entirely new, equips the company with one of the most complete plants of its kind on the Atlantic seaboard. The plant is equipped with three shipbuilding ways and is able to accommodate the largest class of vessels.

PORT IMPROVEMENTS

Grain Elevator, Ft. William, Ont.—Bole Grain Company, Ltd., plans concrete grain elevator. \$500,000.

Grain Elevator, Corpus Christi, Tex.—F. Kell, Wichita Falls, plans concrete grain elevator, \$250,000.

Dredge and Harbor Improvements, Aberdeen, Wash.—\$250,000 has been voted for dredge and harbor improvements.

Grain Elevator, Montreal, Canada.—Montreal Harbor Commissioners plan 10,000,000 bushel grain elevator. Price \$10,000,000. W. L. McDougald, resident.

Wharf and Shed, New Orleans, La.—The Engineering Department, Board of Commissioners, 200 New Court Building, is having plans prepared for a reinforced concrete wharf and shed along Industrial Canal. \$1,400,000.

Wharf Contract, New Orleans, La.—The contract for the reconstruction and rat-proofing of the Robin Street Wharf was let by the dock board to John Riess, New Orleans contractor, on a low bid of \$196,000, work to be completed within 220 days.

Levee, New Orleans, La.—Orleans Levee Board, New Court House Building, has awarded a contract to H. Reynolds, Maison Blanche Building, for a new levee on the left bank of the Mississippi River. Price \$26,801.

Grain Elevator, Owen Sound, Ont.—Owen Sound Elevator Company is having plans prepared for grain elevator, steel and cement, on waterfront. Price \$150,000. R. Patterson, manager. Prices wanted on materials. Private plans.

Harbor Improvement, Midland, Pa.—The General Contracting Corporation received a contract to improve the harbor at the Crucible Steel Company's Midland plant on the Ohio River. About 30,000 cubic yards of material will be removed.

Traveling Crane, San Francisco, Cal.—The contract for furnishing and installing an electric traveling crane in Moccasin Creek Power Plant, Hetch Hetchy Project, was awarded to Pawling & Harneschfeger, 32 Beale street, by the City and County of San Francisco, at a price of \$30,475.

Dock, Warehouse, Etc., New Orleans, La.—Board of Port Commissioners, Suite 200, New Court Building, has had surveys made for dock and warehouse at foot of St. Joseph street, \$400,000; plans are being prepared for wharf apron, heavy timber construction, at foot of Barracks street, \$30,000.

Wharf and Bulkhead, Weymouth (Boston P. O.), Mass.—Edison Electric Illuminating Company, of Boston, 70 State street, Boston, is having preliminary plans prepared for a wharf and bulkhead adjoining proposed power plant, Weymouth. Price \$50,000. Stone & Webster, Inc., 147 Milk street, Boston, architects and engineers.

Two Piers, Virginia.—Two smaller piers will be added to the docking facilities at Old Point by the United States War Department for the accommodation of smaller river and harbor crafts, according to the announcement at the United States Army Engineers' office here. The wharf will be improved also in the project, the entire cost of which will total about \$40,000.

Secretary Weeks has approved tentative plans for the new work, and specifications will be shortly announced. Bids for the job will then be asked of constructive companies.

GOVERNMENT WORK

Dredging, Norfolk, Va.—Specification 4771. Bureau of Yards & Docks, Navy Department, Washington, D. C., plans dredging in Norfolk Harbor.

Barges, Pittsburgh, Pa.—United States Engineer, Pittsburgh, awarded the contract for three steel deck barges to McWilliams Co., Inc., Exchange Building, Memphis, Tenn.; price \$85,082.

Catamarans, Savannah, Ga.—United States Engineer Office awarded the contract for furnishing 25 pontoon catamarans for U. S. dredge Morgan, to Charles Ward Engineering Company, Charleston, West Virginia; price \$22,375.

Dredging, Charleston, S. C.—The Seaboard Dredging Company, Durkee Building, Jacksonville, Fla., was awarded the contract for dredging the western channel and Sampit River, Winyah Bay, by the United States Engineer Office, Charleston. Price \$99,594.

Dredging, Jacksonville, Fla.—The Clark Dredging Company, Miami, has been awarded the contract for dredging in Key West Harbor by the United States Engineer Office, Jacksonville; price \$1.43 per cubic yard; 63,000 cubic yards of dredging.

NEW INCORPORATIONS

The Shamrock Towing Company, of New York, capital \$200,000, chartered under Delaware laws.

Sagua Steamship Corporation, capital \$35,000, of the Atlantic Fruit Company, incorporated at Delaware.

Sydney S. Brees, of Port Jefferson, to do business in boats and ships, has been incorporated for \$50,000.

The Moore & McCormack Company, of Manhattan, has increased its capitalization from \$5,000 to \$500,000.

Tanamo Steamship Corporation, capital \$35,000, of the Atlantic Fruit Company, incorporated at Delaware.

The United Steamship Corporation, of Wilmington, Del., capital \$250,000, chartered under Delaware laws.

Connelly Transportation Company, of Buffalo, capital \$350,000, chartered at Albany, to engage in navigation.

The Quincy Steamship Company, of Manhattan, capital \$100,000, chartered at Albany. H. Goldman, of 120 Broadway, attorney.

The Nautilus Steamship Corporation, of Manhattan, capital \$700,000. Incorporators are: F. V. Barnes, R. F. Wees and J. F. Fessenden.

Shamrock Towing Company, of Manhattan, capital \$10,000, incorporated at Albany. Incorporators: D. J. Dugan, H. H. Lavender and J. J. McGuirl.

The Caddell Dry Dock Repair Company, of Richmond, Va., capital \$250,000, incorporated at Albany, N. Y. Incorporators are: J. B., L. W. and A. Caddell.

The Brighton Dry Dock Company, of West New Brighton, S. I., capital \$250,000, chartered at Albany. Incorporators: J. O. Connor, M. E. Saunders and A. W. Osborn.

The Safety Steamship Company, of Bridgeport, capital \$100,000, to do transportation business. Incorporators are: Arthur Wilkes, Lawrence R. Ahern and David F. Blume.

Commercial Scout Steamship Corporation, capital \$100,000, chartered at Dover, Del. Incorporators are: Linn P. Reed, James H. Tully, and Wallace Ingraham of New York.

American Indian Steamship Corporation, capital \$2,000,000, chartered under Delaware laws, headquarters to be at Tulsa, Oklahoma. The board of directors of the corporation will include bankers, oil men and ranch owners of Oklahoma, all members of American Indian tribes.

FOREIGN ACTIVITIES

Two New Vessels, England.—Messrs. Sir Robert Ropner and Company, West Hartlepool, have placed orders with the Ropner Shipbuilding Company, Stockton, for two cargo boats of 8,500 and 7,700 tons, respectively.

Harbor Developments, Tolago Bay, New Zealand.—The Harbor Board of Tolago Bay, New Zealand, is considering the construction of a wharf and other facilities with sheds and a wool warehouse, estimated cost of the work being £70,000.

Harbor Improvements, Spain.—According to a report received by the Department of Commerce from Ambassador Woods, harbor construction and improvements in Spain are to be undertaken through an appropriation of 18,500,000 pesetas made by the Ministry of Public Works as a Government financial guarantee for loans to be secured by public subscription or otherwise.

Steamer Launched, England.—The twin-screw steamer Murital, built for the Eastbourne Borough Council, Wellington, New Zealand, for passenger service in Wellington Harbor, has been launched by the Coaster Construction Company, Montrose. The vessel is 172 feet 6 inches length overall, 30 feet beam, 12 feet 3 inches deep, and has a speed of 13 knots. Her carrying capacity is from 1,400 to 1,500.

Vessel Launched, Shanghai, China.—The Tze Sui, a vessel designed specially for service on the Upper Yangtze, was launched from the Shanghai yard of the Societe Franco-Chinoise de Constructions Metaliques et Mechaniques, for Chinese owners. She is a twin-screw steamer, 140 feet long, has a loaded draft of 4 feet 6 inches and is provided with ample cargo space, as well as accommodation for a large number of passengers of three classes. She is equipped with two sets of triple expansion engines and has a contract speed of 14 knots.

Finnish Shipbuilding in 1922.—New constructional work at the Finnish shipbuilding yards experienced a further decline in 1922, according to the information collected by the statistical department of the Finnish State Shipping Administration. Vessels under construction amounted to 232 representing a total of 14,099 gross register tons, most of which were lighters. These figures compare with 289 vessels and 25,199 tons in 1921 and 159 and 31,935 tons, respectively, in 1920. Two of the ships under construction in 1922—one steamer and one sailing vessel—were not completed by the end of the year. The total included 20 steamers, 24 motorships and 11 sailing vessels.

STEAMSHIP INTERESTS

The Norfolk, Baltimore, Carolina Line, Inc., will inaugurate, this month, a service to points in eastern North Carolina from Norfolk and Baltimore. One boat will be operated on one round trip a week (starting Tuesday and returning Thursday) between Norfolk and New Bern. A smaller vessel, to be used as a feeder, will be operated on three trips each week between New Bern and Morehead City and Beaufort.

According to W. B. Keene, Director of Traffic, United States Shipping Board Emergency Fleet Corporation, a telegraphic report has been received from Vancouver, B. C., to the effect that the Trans-Pacific Conference Lines in a meeting held recently unanimously adopted and signed the new Trans-Pacific Conference agreement. This agreement is along similar lines to that recently adopted in the North Atlantic under which the lines operating from the Atlantic Coast to the Far East are now functioning, which principally provides for the maintenance of certain rates.

The Red Star liner *Belgenland*, now nearing completion at Belfast, will make her first sailing from New York on April 14, operating with the *Lapland* in fortnightly service for first, second and third class traffic between New York, Plymouth, Cherbourg and Antwerp, which with the cabin-class service will maintain weekly sailings from New York, as at present.

The Red Star Line will, starting April 25 with the *Zeeland* from New York, open a cabin-class service between New York and Antwerp, with calls at Plymouth and Cherbourg eastward, and Southampton and Cherbourg westward on each voyage. The *St. Paul* is the other ship to be used. Each ship will carry in the new service one class of cabin passengers, and third class. The first sailing of the *St. Paul* will be from New York, May 9.

The *Orbita* and *Orduna*, of the Royal Mail Steam Packet Company, are to be converted to one cabin ships, and according to announcement, will in the future carry only cabin and third class passengers. As a result of the classification change there will be a pronounced reduction in the fares.

BUSINESS NOTE

Hanna Engineering Works, 1765 Elston avenue, Chicago, manufacturer and distributor of Hanna riveting machines, air hoists, sand sifters, Mumford molding machines and the Milwaukee Spruce Cutter, is now represented in Detroit and surrounding territory by the Charron Engineering Sales Company, 1002 Real Estate Exchange Building, Detroit, Mich.

TRADE PUBLICATIONS

CALENDARS FOR 1923.—An artistic calendar for the year 1923 has been sent out by the Morse Dry Dock and Repair Company, Brooklyn, N. Y. A feature of this calendar which will be greatly appreciated by shipping interests in the port of New York is a tabulation of high tides, the time of high water at Governor's Island for both A. M. and P. M. appearing in each date square for that day. The calendar is also illustrated

with a photograph of the steamship *Resolute* in dry dock and the *Conte Rosso* backing into a dry dock at the Morse plant.

The Federal Shipbuilding Company, Kearny, N. J., has distributed a calendar on each sheet of which the present month is shown in red and the preceding and coming months in black, giving instant inspection of the current three months. The calendar pad includes each month from December, 1922, to January, 1926, and these pads may be renewed indefinitely as the body of the calendar is of enameled sheet metal.

CORROSION.—The subject of pipe corrosion is discussed in Bulletin No. 3-C issued by the National Tube Company, Pittsburgh, Pa. It is agreed by authorities that oxygen holds the dominating position together with the electrochemical theory in causing internal corrosion. An explanation of this action is given in the bulletin together with the details of the mechanism of corrosion in abstracts from papers which have been delivered before various professional societies. Practical means of preventing corrosion are outlined and the results which may be expected from various methods of water treatment and the like.

MOTORS AND GENERATORS.—Bulletins 126 and 127, covering direct current motors and generators and electric arc welding units, have been distributed by the Burke Electric Company, Erie, Pa. Detailed construction features of the motors and generators are described in Bulletin 126 while No. 127 illustrates the various types and capacities of welding equipment produced by the company.

STOP VALVES.—The R. S. V. stop valve and by-pass made by the R. S. V. Corporation, New York, and its functions are described in a catalogue recently sent out by this company. The device is a drier and superheater of steam for marine and other type boilers. It replaces the ordinary throttle valve and can be connected on the same pipe flange. It has no moving parts and acts like a stop valve.

MARINE OIL ENGINES.—British Kromhout marine oil engines, their history, and construction and application are detailed in a bulletin issued by Perman and Company, Ltd., London, E. C. 3, England. The engine is of the 2-cycle type and is built in units from 9 to 500 brake horsepower. Numerous illustrations are given of installations in various types of ships.

WE GUARANTEE that of this issue, 4,850 copies were printed; that of these copies 3,880 were mailed to regular paid subscribers, 389 were provided for counter and news company sales, 204 were mailed to advertisers, 81 were mailed to employees and correspondents and 296 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 14,700, an average of 4,900 copies a month.

MARINE ENGINEERING AND SHIPPING AGE is a member of the Associated Business Papers, Inc. (A. B. P.), National Association of Periodical Publishers, Inc., New York Business Publishers' Association and the Audit Bureau of Circulation (A. B. C.).

Requests for change of address should reach us two weeks before the date of the issue with which it is to go into effect. It is difficult, and often impossible, to supply back numbers to replace those undelivered through failure to send advance notice. In sending us change of address, please be sure to send us your old address as well as the new one.

"Let's Go!"

WHETHER or not the subsidy bill is passed at this session of Congress, the fact remains that we own the second largest merchant marine in the world and this fleet, on the average, consists of newer and more up-to-date vessels than those of any other country. We might as well make up our minds that these ships, with the exception of four or five hundred of an inefficient type, are not going to be abandoned or scrapped. If we do not operate them, there are others that will, even if they are compelled to do so under the American flag.

We have witnessed, as explained in another editorial in this issue, how one of the largest shipyards in England has established itself in the repair business in New York harbor. But listen to this reported quotation of Sir William Reardon-Smith in a recent issue of *Fairplay*: "Incidentally, he also stated, that his personal representative in the United States, Mr. W. C. Liley, had taken out citizenship papers with the ultimate view of establishing an American subsidiary of the Reardon-Smith Line and purchasing ships for operation under the United States flag; that he believed that these vessels could be operated as cheaply or nearly as cheaply as our British steamers, and will have an advantage of low initial cost and other considerations." Will it be necessary for us to pass through the humiliation of seeing foreign ship-

owners come over here and show us, under the guise of intended citizenship or some other subterfuge how to run our own ships? "Let's go!"

The Ship Repair Work Situation

IN spite of the fact that dry docking charges in the New York district have been reduced to 5 cents a gross ton or practically what they were in 1914, data recently collected by the United States Salvage Association show that the average price of ship repairs, due to the present wage scale and the price of steel, is still about 100 per cent greater than in pre-war days. While the price of dry docking indicates keen competition in this field there are many reasons for believing that the future of the ship repair industry offers opportunities that should not be overlooked.

Although a considerable number of ship repair yards were established in America during the war boom we have still a much smaller proportion of dry dock accommodations per ton of shipping than Great Britain. In 1913 Great Britain had 210 docks for 20,431,500 tons of shipping or about 93,000 tons per dock. There were in 1919 on the coast of the United States 44 docks against a total of 13,000,000 tons of shipping or 295,000 tons per dock. Figures are not available for docks installed since 1919 but we have still a long way to go before our repair facilities per ton of shipping equal those of England.

No doubt the relatively high cost of repairs in American yards has been the controlling reason why so large a proportion of this work has been done on British and foreign vessels at their home ports. Nevertheless at least one firm of British shipbuilders and repairers has shown its confidence in the belief that much more British and foreign shipping might be satisfactorily repaired in the United States instead of deferring the work until arrival in home ports. We refer to Swan, Hunter and Wigham Richardson, Ltd., who recently became associated with the New York Harbor Dry Dock Company of Staten Island, N. Y.

As to the prospects for home work, there is the definite circumstance that practically every American vessel that has been tied up for lack of trade will certainly need overhauling and repair work before it can be operated again. In connection with this, the most probable shipping development in the near future, as explained in another editorial, will be the conversion of quite a number of steamers to motorships.

Still further, the provision of the recently enacted tariff law requiring American shipowners to pay a 50 percent tax

same powered engines and the same size auxiliaries it will probably make a decided difference in the initial costs.

This is probably what will happen, for the Government vessels suitable for conversion may be divided into three or four classes and the Shipping Board is considering the advisability of appointing an expert committee to standardize the sizes of engines, motors, pumps and other auxiliaries so that prospective purchasers may be furnished with standard specifications that will have the approval of an authoritative body. As may be easily seen, such specifications would have a decided effect on the price of electrically driven auxiliaries.

Another matter that should not be overlooked in deciding between the steamer and the motorship is whether or not the steam installation in the existing vessel is what it should be. Professor Chapman has assumed an economically designed steam installation but it is a known fact that the machinery in many Shipping Board vessels does not fit the characteristics of the ships.

When the Shipping Board completes its investigations, however, there can be no reasonable doubt that the Diesel installations specified will represent excellent practice both as to main and auxiliary power. Thanks, therefore, to the surplus Government-owned tonnage, it will be possible to obtain the best type of motorship cheaper in America than anywhere else in the world, and this, in our opinion, is a good and sufficient reason to believe that important developments along this line will occur in the near future.

Adoption of Uniform State Marine Insurance Laws Recommended

THE Chamber of Commerce of the United States has sent out a circular letter under date of February 10 recommending the adoption by the various states of uniform marine insurance laws based upon the underlying principles of the Model Marine Insurance Act of the District of Columbia. State legislatures should give this recommendation their earliest attention because American marine insurance companies are meeting foreign competition with the greatest difficulty due both to the conflicting laws of the states and to unjust restrictions and handicaps.

Congress realizing the injustices of these conditions passed the model insurance bill hoping that the several states would modify their laws to conform to it. The fundamental ideas of the bill are as follows: To provide greater freedom on the part of American companies to co-operate through syndicates and mergers. To establish the multi-field insurance principle, so that American fire, marine and fire-marine insurance companies may be free to transact all kinds of insurance other than life. To substitute a system of net profits taxation in place of the system of taxing gross premiums. To enlarge reinsurance facilities. To remove the limitations on the financial powers of companies which hamper operations in foreign fields.

It appears self-evident that there is no logical argument against the adoption of a uniform marine insurance law within the nation providing, of course, that a good model to work on is available. And, in this connection, we are glad to be able to say that the Committee on Merchant Marine and Fisheries of the House of Representatives in preparing

the Model Insurance Bill of the District of Columbia made a very thorough and exhaustive investigation of the whole subject having in mind the fact that they were forming a basis for the states to follow.

Missing Our Great Opportunity

THE Department of Commerce reports that the idle tonnage of the world has been reduced by 2,000,000 gross tons during the year 1922. American merchant ships, however, have failed to make any gain, the idle tonnage as of January 1, 1923, being 4,411,000 gross tons as compared with 4,314,000 gross tons on January 1, 1922.

England in the meantime has reduced her idle vessels by 951,000 gross tons and her shipowners have recently placed substantial orders for new ships. This shows that there is not the world surplus of efficient vessels that insidious propaganda would lead us to believe. In fact, of the 8,955,000 tons of idle tonnage remaining, approximately half of which is tied up in our rivers and harbors, the American vessels alone practically represent the ships that are not obsolete and unfit for competition in the world trade.

The answer is that shrewd English shipowners are aware that the price of new construction has reached a minimum and that world trade and conditions in general are getting better. The prompt acceptance of the terms laid down by the American Debt Commission by the British Government and the fact that this settlement will probably be endorsed by the American Congress by the time that this editorial is printed should have a far-reaching effect on business stability both here and abroad.

What are we going to do about it? Are we going to continue to sell the world short, are we to sit quietly by and watch an inflation of domestic business without providing a governor in the shape of increased foreign trade and American ships to carry it in for the surplusage of our products that is bound to accrue? The Shipping Board will sell first class ships as cheap if not cheaper than they can be bought anywhere in the world, a great subsidy in itself. It has paid for the education of a number of operators and made them agents for the cream of the fleet. Every reasonable request for equipment or fittings that would increase the economy has been provided at the country's expense. All that is lacking is a definite constructive policy on the part of the Government.

Now if Congress evades a decision on the shipping bill at this session, the Shipping Board, knowing that no one has any business to operate Government ships unless he intends eventually to become their owner, should definitely establish a policy not to parallel routes covered by privately owned lines and then it should put the same energy that it has expended in trying to secure favorable legislation into forcing the operators of Government tonnage who have been nursed along through the depression to become financially interested in the vessels that they are running.

The fact that the world's idle tonnage is rapidly decreasing is a strong indication that shipping is on the upturn. If we allow ourselves to become discouraged at the procrastination of Congress, we will miss the greatest opportunity this nation has ever had to assume the commercial and moral leadership of the world.

Give American Shipping a Square Deal!

Why Single Out Shipping and Shipbuilding Among All the Industries of the Country to Be Without Protection?

By "Old Scotch"

A FRIEND recently, in discussing outstanding events in his life, described his saddest experience. It appears that he was orphaned at the early age of six, and was taken over by a relative to raise. Arriving at his new home in November, it was not long thereafter that he attended the Christmas Eve festivities at the Sunday school to which he had been affiliated. The Christmas tree was brilliantly lighted, and laden with presents for both young and old. Laughter, song and joy reigned supreme as customary on such occasions.

As the religious ceremonies were completed, the superintendent in a resonant voice called out the names of every scholar and teacher, and, amid applause, some appropriate gift was handed to each. The one exception in this entire audience was this poor little 6-year-old orphan, whose name had been overlooked either purposely or accidentally, it matters not which, so far as his feelings were concerned. Imagine what thoughts were flashing through that poor child's mind as he wandered home that Christmas Eve in the snow. He told me that for years his mind was embittered by the memory of the overwhelming injustice placed upon him that evening.

Are the shipping interests in this country to be placed in the mental attitude of that poor 6-year-old orphan? is the question now up to the Senate of the United States. Are we in years to come to be embittered against our own Government for singling us out among all the industries of this broad land to be the step-child and helpless orphan? Gentlemen of the Senate, the bare facts of the helplessness of the shipping interests in conducting the foreign trade of this country have been placed before you. In spite of many efforts to camouflage the real situation, you cannot, if you believe in a square deal, sidestep the issue.

LIMITED EXPENDITURE WILL RETAIN GREAT SUMS IN THIS COUNTRY

Such wild statements as: "The pending bill is designed to turn over \$750,000,000 to the Shipping Trust" do not go with an enlightened public. You know in your minds that such is not the fact. You have already limited the total expenditures to \$30,000,000 a year for a period of ten years, and you know that there is no such thing as a shipping trust in this country. If you will reverse that statement and say that the defeat of this bill will turn over \$750,000,000 of the money of your constituents to foreign shipping trusts in the next ten years, you will be approaching the truth, except the amount involved will be perhaps three times that sum. You know from your own Congressional investigations that there is a very potent trust in foreign shipping, and you also know from the same investigations that there is nothing even resembling a trust among the shipowners of your own country.

You know that this term "subsidy" which is not even used in the shipping bill, but only used by the critics of the measure, is nothing more nor less than a protective tariff applied to the shipping industry, and that it is the only practicable method of giving protection and encouragement to the merchant marine.

ONLY SUFFICIENT PROTECTION TO COMPETE WITH FOREIGN INTERESTS REQUIRED

Is there any out and out free-trader in your ranks? My impression is that every one in this country believes in a

tariff to protect the industries in which he is interested be they agricultural, mining or manufactured products. The only differences on the subject of the tariff, between the two great political parties, are in the relative protective rates needed to allow different industries to compete with like industries abroad.

The old economic saw of: "Let him who does it cheapest do our work," does not apply in any branch of American industry which has to compete with foreign output. It is un-American and contrary to our policies which have made us the richest nation on earth. Is it possible that you want to single out our merchant marine as the lone "orphan" upon which to apply this anti-American policy of sink or swim according to economic conditions?

All protective policies which we have introduced in this country have paid indirectly in the building up of the general prosperity of the country. Our merchant marine in its present condition will, if this bill is enacted, pay vast dividends in increased trade abroad beneficial to farmer and manufacturer alike, besides keeping millions of dollars at home for the freight and insurance moneys which must otherwise go abroad to our rivals. In addition, do not overlook the fact that it will actually save money to the Treasury, and that *direct* taxes will be reduced rather than increased.

This proposition is as simple as A B C, yet it has not been properly explained to your farmer constituents. The very fact that an annual sum of \$30,000,000 expended as a protective tariff to shipping, making it possible for Americans to operate many of our idle ships, will give us a market for the sale of these ships, which otherwise must swing idly at their moorings and become disintegrated by the ravages of time. The enhancement in value of these otherwise idle ships will put in the Treasury at the lowest calculation not less than two dollars for every dollar invested in the annual reserve tariff paid to the shipowner.

Was there ever a better straight-out business proposition put up to the American taxpayer?

Where is there a farmer or a tradesman in this country who would not immediately embrace an opportunity of this kind in his own business?

SHIPPING BILL MISREPRESENTED

In conversation with several friends who have recently made trips through the farming communities of the said West, I learn that there is an alarming condition among the citizens there on account of their inability to pay the huge taxes placed upon them by the federal, state and local authorities. They have been taught that this so-called "subsidy" bill is another great increase in their federal taxes. Naturally, like instituting economy among your wife's relatives, they immediately clamor for reform in the industry which they think affects them the least. Tell them the unvarnished truth about this shipping situation, let them know that this bill is a saving and not an additional expenditure, and their good common sense will bring their approval to your action in voting for this measure.

Tell the farmers in the South of the statement made by one of their great senatorial leaders, that the lack of American ships in 1914-16, cost them over one billion dollars in cotton alone.

Tell them also of the two authoritative statements issued

by competent authorities within the past week. The first is that the world's shipping business has increased, as evidenced by the fact that there were over 2,000,000 tons less of idle ships in the world on January 1, 1923, than there were on the corresponding date one year ago. The United States was alone in having more idle ships than in the previous year. The second statement is that American exports actually decreased over \$650,000,000 during the year 1922. Couple these statements and use your own logic as to the ultimate result for our American industries.

COST OF SUFFICIENT MERCHANT MARINE LESS THAN PRESENT FIASCO

There has recently been appropriated the sum of \$50,000,000 to pay the losses of Government operation of merchant ships, and to care for the laid-up ships. Compare this to the sum of \$30,000,000 which is proposed to aid a sufficient merchant marine when placed in private hands. Let the farmer constituent consider that difference when he moodily contemplates his ever rising tax bill.

Assistant Secretary Roosevelt, a chip of the old block,

recently stated in a public address, just what his illustrious father has often stated, that our national safety depends upon the maintenance of a sufficient merchant marine just as much as it does upon the fighting ships of the Navy. They are inseparably linked, each dependent upon the other. Can we fight for our national safety with only one leg upon which to stand?

Shorn of all technicalities, the foregoing are statements of the underlying facts in connection with the shipping problem now before the Congress of the United States. Can a tenable argument be given as to why the bill should not be enacted into law? Many misrepresentations have been brought forth but they cannot withstand the logic of bare facts. A rising tendency towards Government ownership and operation is in evidence, but our experience with the railroads in war times should be sufficient to steer us clear of that procedure with shipping.

Weigh these facts and *give us a square deal*, which when conditions are known and matters carefully analyzed is what the American public always demands of its legislators.

Do not treat us like an orphan!

National Merchant Marine Association Holds Fourth Annual Convention on February 7 at Washington

Representatives of Commercial Organizations, Commonwealths and Cities in Convention Assembled Petition Congress for Speedy Action on Shipping Bill

THE fourth annual convention of the National Merchant Marine Association was held in the Rose Room of the Hotel Washington, Washington, D. C., on February 7. Senator Joseph E. Ransdell of Louisiana, president of the association, opened the convention with a stirring address on the tremendous importance of the merchant marine to the American people. He said that it is going to take all the influence of all the business organizations and maritime associations to build up a favorable public opinion in regard to shipping.

"The subsidy bill has the strongest prospects for a speedy passage," Senator Ransdell said, "but, if the bill is enacted into law"—and he believed that it would be—"it will be essential to maintain this association because a clearing house will be necessary to help mold and maintain public opinion. Should the measure fail it will be all the more necessary for the association to conduct an educational program."

NAVY NEEDS THE MERCHANT MARINE

Colonel Theodore Roosevelt declared that civilization is and always has been based on transportation and communication and that the countries that are the highest developed today are those having the best means of communication.

"The outstanding characteristic of the Roman Empire and the primary factor that built it up and held it together was its splendid system of roads and its fleets of galleys."

The Navy, Colonel Roosevelt pointed out, has the prime function of preserving communication by sea. It is also our first line of defense, but the value of a merchant marine from the standpoint of defense has always been recognized. By the limitation of the Navy the importance of the merchant marine is greatly increased, a point brought out by Secretary Hughes at the Disarmament Conference when he said that the importance of the merchant marine is in inverse ratio to naval disarmament.

The merchant marine is a valuable complement to the Navy in furnishing light cruisers and scouts. It maintains in time

of peace vessels that otherwise would have to be kept in idleness at great expense for the purpose of serving as colliers and supply ships in time of war. We are not a military nation and without a merchant marine where are we to draw the men to man our warships in time of war when a rapid expansion of the Navy is imperative?

The ship subsidy bill is also necessary in order to maintain our high standard of living, declared Colonel Roosevelt. A republican form of government depends on a high average of citizenship and we want our sailors to share this standard. The merchant marine needs the Navy in time of peace, the Navy needs the merchant marine in time of war, and both are needed by the country at all times.

SHIPPING BILL FROM FARMER'S STANDPOINT

The farmer's interest in the shipping bill was discussed in a speech prepared by Senator Wesley L. Jones, which was read on account of the senator's absence by Winthrop L. Marvin.

The farmer more than any other one class in the country needs the immediate passage of the shipping bill, was the conclusion of Senator Jones. It was essential, he pointed out, that our farm products find markets abroad and that their profitable export depends upon reasonable rates and prompt service.

"If there are no ships," Senator Jones said, "there is no market for this farm surplus and this very fact reduces the price for the whole surplus. If foreign ships alone are available to take his crops, the farmer must await their pleasure or convenience and he must pay such freight as they see fit to charge."

Senator Jones said special appeals had been made to set the farmer against the Shipping Bill, why, he did not know. One of the favorite assertions was that the merchant marine payments would go only to wealthy shipowners—an unnamed and intangible shipping trust.

The great bulk of the merchant marine fund, or subsidy money, Senator Jones said, would go to men who will buy

or build American ships and run them in competition with already established foreign ships or lines. "It will lead to American transportation instead of foreign transportation for the products of the American farm," he added, "and what American farmer does not think that is a valuable thing to have?"

"Not only does it furnish him transportation at reasonable and stable rates, but it establishes shipyards furnishing employment to labor and a market for his products and the employment of capital and labor in many different ways.

"The high rates which the people had to pay before American ships were built, went largely to alien ships owned or controlled by great trusts over which we had no control. If we had built a merchant marine, our farmers and business men would have been saved hundreds of millions of dollars that went into the coffers of these foreign shipowners and would have been saved hundreds of millions of tax burden. In addition, much of this money would have been spent at home in the development of our interests and the employment of our own labor, thereby adding greatly to the domestic market for the farmer's products."

MERCHANT MARINE NECESSARY FOR FOREIGN TRADE

Colonel Myron W. Robinson, president of the American Manufacturers' Export Association, declared that if we want to place American goods in the markets of the world then it is necessary to have American ships sailing the seven seas. The whole world, he said, admits that foreign trade is vital, our own people admit it whether they be manufacturers, bankers, farmers or merchants.

The least disturbance on foreign shores today, said Colonel Robinson, is at once shown in our daily business. Our foreign business is much smaller than our domestic business, but still—"It is the tail that wags the dog." Those who read the newspapers of today and cannot see beyond our own shores are certainly near-sighted. It is not only the necessity of foreign trade but the effect of this trade upon domestic business that makes it so essential.

Our economic body must stand on the two legs of transportation, inland and ocean, declared Colonel Robinson. One of these legs, the merchant marine, needs help and that help is the so-called ship subsidy bill. As a matter of fact, all other industries have been generously helped and in each case that aid has been no more nor less than a subsidy.

AMERICAN SHIPS RECOMMEND THEMSELVES

Mr. Frank C. Munson, president of the Munson Steamship Lines, spoke of the present service of our passenger vessels. He declared that the combined passenger and freight ships popularly known as the 535's were vessels to be proud of and that they were operated with the highest efficiency, both on the Atlantic and Pacific.

Referring to the subsidy bill, Mr. Munson stated that if that measure fails, our passenger vessels cannot continue to run and also that the freighters running in conjunction with them and their feeder ships will also have to be discontinued. As an illustration of the general lack of faith in Congress supporting American shipping he said that the International Mercantile Marine Company had built a number of ships in British shipyards since the close of the war. Mr. Munson pointed out the present filibuster as evidence of the influence of foreign interests through large amounts of money spent on propaganda.

On the other hand, Mr. Munson believed that the passage of the subsidy bill would make it possible to dispose of a large number of vessels to private owners. He also thought that it would stimulate the conversion of steamers to motorships and, in this connection, he explained that the Shipping Board would appoint a committee of experts to expedite that project and that there would be many who would take advantage of it.

SHIPPING AND SHIPBUILDING A NATIONAL ASSET

"It is not tolerable that we should, either in peace or war, be dependent on any other nation for our international trade conditions," said Robert Haig, vice-president of the Sun Shipbuilding Company, "and to us, now that naval disarmament is likely to reduce our warships almost to the vanishing point, the necessity of a real mercantile marine is vitally important.

"At all times productiveness in any quarter is governed by the transportation to be obtained," said Mr. Haig, "and where transportation is lacking or inadequate, business languishes, the country's assets are impaired and the people suffer through lack of work, food and fuel. Transportation is the life blood of a nation, and a look abroad will demonstrate how keen the other nations of the world are to maintain and develop their marine transportation.

"Shipping, neither here nor elsewhere," said Mr. Haig, "can not continue unless it is supported by well equipped, up-to-date shipyards, and shipyards will not continue to exist and do good useful work unless they can find employment to sustain the staffs necessary. Shipbuilding is a complex art, requiring for its execution educated and specially trained men. If shipbuilding should be allowed to decline, as it did years ago, these men will eventually drift into other channels and the art and practice of shipbuilding, with all the labor research of years, will be lost."

Mr. Haig said it was abundantly proved that shipyards could not be improvised over night and told of the great work done during the war by the private yards in building and repairing and in training personnel. He pointed out that of all our industries, shipping was the one unprotected one. Mr. Haig then asked why such a vital link in the nation's defense should be ignored.

SUBSIDY BILL WILL REDUCE COST OF OPERATION

Not the least interesting of the addresses delivered at this convention was the speech of the Honorable S. G. McLendon, Secretary of State of Georgia. Mr. McLendon quoted President Harding in his message to Congress, November 21, 1922, as informing the country that our fleet of merchant ships had cost three billions of dollars, that these ships were worth only a fraction of that cost, that in operating less than one-third of our Government-owned ships the people were losing \$50,000,000 a year and that, under the bill now pending, this loss would be reduced from \$50,000,000 to \$20,000,000.

Mr. McLendon declared that it was the first duty of the Government to get rid of the public ownership of any business. It was a Democratic congress, he pointed out, that granted the first subsidy of \$400,000 a year to the Collins Line and this aid, he stated, had been sufficient to enable the American line to beat the Cunard Line. The Democrats, he said, were opposed to a ship subsidy now because of inherited prejudices which they should abandon for the good of the country.

COMMERCE OF UNITED STATES A TREASURE HOUSE FOR FOREIGN SHIPS

Commissioner Edward C. Plummer of the United States Shipping Board pointed out that for years propaganda in the interest of foreign ships, which had found such a treasure house in the foreign commerce of the United States, had pursued a devious course among our people with little difficulty. Now he said the people were awakened to the vast national interests which this question of an American merchant marine involves, and to the fact that the commercial independence of this country,—to say nothing of our national security—demands an adequate fleet of merchant ships under the Stars and Stripes.

"This growth of American business in South America, which has given much employment to Americans, is wholly—

mark, I say wholly—due to the fact that since the war we have put American ships into the service between those countries and the United States. There had been ships plying between Brazil and the United States for fifty years, but they were foreign ships, and the foreigners got the business which is now coming to us. That is the statement of Sir John Thornycroft, and surely no opponent of American shipping would think of questioning the word of a titled Englishman!

"Take the case of our services from the Pacific States to the East Coast of South America. Before our vessels were put on that route business there was negligible. We started with freighters and small cargoes. The business sought by the Shipping Board has so developed that already we have supplemented those freighters with combination freight and passenger ships, and the growth of this business, constant and healthy, is of great benefit not only to the people of the United States but to the people of South America whom we serve.

"Adequate water services between two countries are always beneficial to both countries, and what both of our South American lines have accomplished is a benefit to the South American countries served as well as to the United States."

COMMERCIAL AND FINANCIAL SUPREMACY DEPEND ON SHIPPING

"Command of the seas," declared Congressman George W. Edmonds, "meant in the olden times as it does today; commercial and financial supremacy, and as a consequence marked the most powerful nation. How marked in history are the names of Phoenicia, Carthage, Athens, Rome, Venice, Genoa, Portugal, Spain, Holland and England, for a short time the United States, and again by the indifference of ourselves Great Britain, and how all history of the non-maritime nations sinks into oblivion and fable when compared with our own knowledge of those various 'Mistresses of the Seas.'"

"The merchant ships of all nations were not only a safeguard to the integrity of these nations, but were the pride of their people so much so that almost as far back as history exists it will be found that all governments gave every necessary assistance to forward the interests of their merchant marine.

"As an aftermath of the great war," said Congressman Edmonds, "we again find ourselves in possession of a merchant marine, not well balanced in the types of vessels, but beyond question the second merchant marine in tonnage. We find that to operate these ships, as it is believed American ships should be operated, and on account of the higher cost in the United States compared to other nations, and more than anything else on account of the ship subsidies, ship-building bounties, preferential railroad rates, high postal subventions, and other assistance paid to their merchant marines by our principal competitors, we are forced either to be in the position of letting our ships lie in idleness, and using other ships for our carriage or of giving to our ships such assistance as we find necessary to equalize the differences.

"It appears that owing to unfortunate scandals which have arisen in the past, about certain subsidies which have been given to favored steamship lines, the paying of subsidies by the general Government to shipping has been generally unpopular among people who reside in sections of the country not in touch with shipping, and yet these same people have been assisted by subsidies ever since the beginning of this Government. What was the enormous land grants to railroads but a subsidy, and it was these land grants which opened up the entire Western and Middle West of the United States? What are the Government expenses on rivers but subsidies? Has not the Government spent millions of dollars in destroying the pests and improving conditions on farms, are they not subsidies? Recently we authorized \$300,000,000

for good roads, and nearly one-half of this is already spent or authorized, is not this also a subsidy? And so you could find by investigation that the Government expends vast sums of money, all of which can be classed as aids to special interests.

"The experiences of the past few years," Congressman Edmonds pointed out, "has shown conclusively that our Government as it is situated, is not flexible enough to enter into the business enterprises in which foreign competition is a principal factor. Decisions must be met on a moment's notice and can only be made by a management that is capable and has authority to do so. A Government department or even an executive officer cannot have such flexibility conferred upon them as will be possible in a private corporation. International competition does not lend itself easily to rules and regulations. One thing is particularly fortunate at the present time that we have now several years' experience in the world's shipping business and established certain connections which will assist in the proper conduct of the business. All of this helps and will assist us in retaining a considerable percentage of our tonnage. In the meantime it must be presumed that the continued loss occasioned by the operation of these vessels under Government ownership, together with the depreciation, will continue until the merchant marine of our country dies either from lack of appropriation to continue this loss, or the old age of the vessels will render them obsolete, and we will gradually drift back to allowing our competitors to do our carrying business. Control of the terminal carriage business in our export trade means control of the prices of the commodities exported. Certainly those opposed to the subsidy bill cannot but view with alarm the making of the prices for our own commodities by our foreign competitors in the same."

UNITED STATES SHIPPING BOARD EMERGENCY FLEET CORPORATION

FUEL DEPARTMENT

SUMMARY OF GENERAL INSTRUCTIONS TO CHIEF ENGINEERS FOR HANDLING BUNKER AND CARGO FUEL OIL AND COAL

I. ORDERING.

A. As much advance notice as possible shall be given by the Master (preferably 48 hours) to the port representative of the Emergency Fleet Corporation or Agent for the vessel.

B. If any trouble exists with burning equipment, tanks, coils, also if any tanks contain any fuel oil not usable, same should be reported at time request for oil is made.

C. Avoid Sundays, holidays, or night deliveries as much as possible.

D. If tugs are necessary to furnish steam, same should be specified when ordering fuel oil.

E. State exact position of vessel and time vessel will be ready to give barge clear berth.

F. State size and type of filling connections.

II. RECEIVING.

A. Bunker tanks should be reasonably free from water, sediment, and other foreign substance and otherwise be in proper condition to receive oil.

B. It shall be the duty of the Chief Engineer, or one of his assistants who is thoroughly familiar with the vessel's fuel-oil system, to be on board at all times when the vessel is receiving fuel and provide the services of sufficient personnel to satisfactorily handle lines and make hose connections.

C. It is imperative to have an understanding with the captain of the barge or deck foreman about signals for "starting," "slowing down," and "stopping."

III. BARGE DELIVERIES.

A. The exact time should be taken when the oil barge comes alongside, when pumping starts, and when pumping has been completed.

B. Ascertain if barge is calibrated and if calibration tables are on board.

C. Before pumping starts, the Chief Engineer or assistant with the barge captain, will gauge and take temperature of the oil. After delivery is complete the engineer and barge captain will again gauge and take temperature of barge tanks and agree on the amount of oil delivered by careful checking of measurements against the calibration tables.

D. If no calibration tables are on barge, the Chief Engineer will note on the delivery tickets the measurements of the barge tanks and the temperature of both opening and closing gauges. Chief Engineer will then sign receipt for one lot of oil delivered and show temperature. He must also note on receipt any delay incident to the delivery and show quantity as shown by measurements of vessel's tanks.

E. In cases where bunkers are taken at the oil docks, the Chief Engineer shall go ashore or send a competent assistant to witness the opening and closing gauges of the shore tanks, take temperature of the oil, and compare gaugings with calibration tables of the shore tanks to determine quantity received.

IV. SAMPLE.

A. When the Emergency Fleet's inspector is not present the Chief Engineer shall see that a fair sample of the oil delivered has been taken. He shall insist that supplier furnish him with at least one pint of the sample, same to be sealed and initialed by the supplier's representative and the Chief Engineer, and be retained by the Chief Engineer at least thirty days. If any trouble is found with the oil, the Chief Engineer is to turn the sample, with seal unbroken, over to the Emergency Fleet Corporation's representative or agent of the vessel at the first port of call for analysis, and make a written report as to the quality and trouble with the oil.

B. Bunker tanks are to be sounded before delivery and after oil has had time to cool. This will give a further check on the amount of oil received. If any great difference in figures, the fact should be promptly reported to the port representatives.

C. For making temperature adjustment in ascertaining net quantities of fuel oil, use the divisional method. Multiply difference in temperature above 60° F. by .0004, add 1 and use result as divisor in dividing the gross barrels; the product will be the net barrels. For example, if 8,000 barrels of oil were received at a temperature of 100° F. the temperature correction would be worked out as follows:

$100 - 60 = 40$ degrees difference in temperature.
 $.0004 \times 40 = 0.016$ plus $1 = 1.016$; $8000 \div 1.016 = 7874.01$ barrels, or actual net quantity of oil received at 60° F.

V. COAL BURNERS.

A. When taking coal bunkers alongside coal piers in the absence of the Emergency Fleet Corporation's inspector, the Chief Engineer shall keep a record of the number of pier cars dumped through the chutes into his vessels and should in every case procure from the pier superintendent a copy of dumping ticket, which ticket should show number of cars dumped and weight of each car.

B. When taking coal bunkers from lighters, scows, or barges, the Chief Engineer shall have some one aboard vessel check the quantity of coal received.

C. The Chief Engineer should use the following cubic capacity, which will be used in figuring the amount of coal in bunkers: 42 to 45 cubic feet per ton of 2,240 pounds. Fine coal will usually run 42 cubic feet to the ton, and large lumps will usually equal 45 cubic feet to the ton. It will be necessary for the Chief Engineer to judge the sizes of the coal in order to get a more accurate check of bunkers received.

D. The Chief Engineer shall give careful study of the capacity of his coal bunkers at different levels and to the manner in which the coal is trimmed in order to give him a further check on the quantity he receives.

E. The Chief Engineer should know the quality of coal that has been ordered and be at least partly familiar with its characteristics, and should himself inspect or have a member of his staff inspect the coal as it comes aboard for any unusual amount of bony coal, shale, dirt, or any other foreign substance. If it is found that the coal is not up to the standard quality of the coal he is supposed to receive, he should at once protest to his port representative. If he is compelled to take the coal, he should note poor quality on the delivery ticket and on his log.

GENERAL.

A. Chief Engineers should turn over all fuel oil in vessel's tanks as often as possible—at least every 30 days, especially in double bottom and peak tanks. Fuel oil allowed to age in vessel's tanks generally becomes contaminated.

B. Special attention should be given at all times to the danger of allowing any oil to enter the waters of the harbor.

C. Every precaution should be taken in using water ballast to avoid mixing water with fuel oil.

D. Special effort should also be made to minimize amount of smoke escaping from anchored or docked vessels.

LOADING AND BUNKERING OF OIL.

The Master will be held strictly responsible for the enforcement of the National Fire Protection Association rules for receiving bunker oil, as quoted below:

Before commencing to load oil, all signal bells, gongs, etc., shall be tested to insure working condition.

Hose used for filling or discharging shall be of the flexible metallic type; couplings shall be equipped with sleeves or some other approved device for the purpose of taking up shock and preventing rupture of connections through tension, in the event of a vessel moving during filling operation.

While oil is being received or discharged, no open lights, smoking or electrical apparatus liable to spark shall be permitted within 50 feet of an oil hose, tank, compartment containing a tank, or vents. Storage tanks shall be watched for leaks.

Hatches on tankers shall be kept closed during loading or discharging. Tugs or other steam vessels shall not be allowed alongside when hatches are open.

If practicable galley fires in tankers shall be extinguished; otherwise openings to the galley shall remain tightly closed during loading or discharging.

On tankers there shall be no fire in the donkey boiler, and all drafts and openings shall remain closed and the fire room hatches covered.

Loading or discharging should, as far as possible, be carried on in the daytime. When carried on at night no lights should be permitted on the deck. Lights shall be in clusters and suspended in the rigging at a safe distance from deck and the wires shall not drag across the deck.

The Chief Engineers shall give close attention to any special instructions issued by the Emergency Fleet Corporation that may affect bunkering at certain ports.

JOSEPH E. SHEEDY,

Vice President, Emergency Fleet Corporation

Comparison of Steamships and Converted Motorships

By Lawrence B. Chapman*

The following comparison has been made in view of the keen present day interest in the possibilities of converting idle Shipping Board vessels to motorships. There are a large number of these idle ships that will probably be thrown on the market in the near future at relatively low figures. Some of these ships will be converted to motorships while others will be refitted and repaired to operate with the existing steam machinery.

IN order that the ships that are converted to motorships should be able to compete with the steamers, the ships for conversion should sell at a somewhat lower price per ton. Shipowners hesitate to adopt Diesel machinery because of the larger capital charges of the motorship compared to those of the steamship; and, unless they can see a possibility for a gain over the steamship, many will hesitate to buy these ships and convert them to motorships.

The following comparison has been worked up to throw some light on the comparative performances of the motorship and steamship with different initial costs and on different trade routes. A hypothetical ship of 10,000 tons deadweight has been used and various prices per deadweight ton have been used as outlined below. The comparison is based on annual operating expenses and profits on given trade routes, which is the only way any true comparison can be made.

Certain general assumptions have been made for the assumed ship and the calculations then carried through in as consistent and unbiased a manner as possible. While almost countless minor modifications and variations can be made in the general assumptions, data and conditions of operation, the comparisons tabulated in Tables II and III indicate in a general way the results to be expected on voyages of 5,000 and 10,000 miles. If actual operating data or costs are available that differ from those used, changes can readily be made in the table for a particular case. The main feature in any comparison of this sort is to account for all operating expenses and allow the proper cargo deadweights and fuel consumptions.

In working up the comparison, the gross deadweights have been modified for each ship according to the weight of the machinery installed. This of course reacts to the disadvantage of the motorship, especially on short voyages. On the other hand, the net cargo deadweight used in calculating freight rates allows for the weight of the fuel and feed water required for the voyage in question. This is decidedly to the advantage of the motorship and shows up especially in the comparison of tons carried per year on the 10,000 mile voyage (line 15 in Table III). A twin screw installation has been used for the motorship as this allows higher revolutions per minute and consequently a lighter machinery installation, for a given propeller efficiency.

MAIN PARTICULARS OF SHIP

The dimensions and other characteristics of the standard ship chosen for the comparison are given below. It does not represent any existing ship but merely one assumed for the comparison.

Length between perpendiculars.....	420 feet
Beam	58 feet
Depth	35 feet
Draft	26 feet 6 inches
Displacement	14,380 tons
Block coefficient	0.78
Sea speed	10½ knots
Net tonnage (about)	4,700
Weight of hull and equipment.....	4,000 tons

Four types of machinery installations have been used as follows:

- (1) Four cycle Diesel propelling machinery with steam engine room and deck auxiliaries (twin screw).
- (2) Four cycle Diesel propelling machinery with electric engine room and deck auxiliaries (twin screw).
- (3) Geared turbines, watertube boilers with oil fuel (single screw).
- (4) Triple expansion engines, Scotch boilers with oil fuel (single screw).

The geared turbine installation has been purposely assumed as good service practice and the reciprocating engine somewhat worse than might be expected, in order to cover a wider range in the comparison.

ASSUMPTIONS

The following general assumptions have been made:

- (1) Cost of steamship for conversion to motorship = \$10 per deadweight ton "as is."
- (2) Cost of steamship to operate with existing steam machinery = \$25, \$30, \$40 and \$50 per deadweight ton.
- (3) Cost of converting from steam to Diesel machinery:
 - (a) Keeping all steam engine room and deck auxiliaries = \$350,000.
 - (b) Changing all engine room and deck auxiliaries to electrically operated = \$500,000.

The conversion costs are approximately the accepted figures today and agree very closely with figures given by Mr. J. L. Ackerson in his paper before the Society of Naval Architects and Marine Engineers in November, 1922, which appears elsewhere in this issue. The costs per ton for the steamship are for the ship ready for service which will include a charge of between \$5 and \$10 for overhauling and repairing.

- (4) Days lost per year for repairs, overhauling, and docking = 30.

- (5) Fuel carried is 20 percent greater than the calculated required amount for the voyage. The fuel cost that has been allowed is 5 percent greater than the calculated amount.

- (6) Time in port increased 10 percent over the calculated time for handling cargo to allow for tides, holidays and delays.

- (7) Time at sea increased 5 percent over calculated time to allow for bad weather.

- (8) Ships assumed fully loaded to draft marks.

- (9) Life of converted motorship taken as 20 years (5 percent depreciation) and life of steamship after a general overhauling taken as 14⅓ years (7 percent depreciation).

- (10) Insurance on steamship has been taken slightly higher than converted motorship as shown by line 17 in Tables II and III.

- (11) Repairs, maintenance, painting and overhauling of the ship and machinery have been assumed 5 percent of original cost per year for the motorship and 6 percent for the steamship.

- (12) It is assumed that a rate of 30 tons per hour can be maintained in loading and unloading cargo. This is at the rate of one draft per minute with a draft of 1,120 pounds,

*Professor of Naval Architecture, Lehigh University, Bethlehem, Pa.

which can easily be maintained. Allowing 5 hatches in operation for 10 hours per day, 1,500 tons per day are handled. (See article by the writer in the February issue of MARINE ENGINEERING AND SHIPPING AGE.)

(13) The net tonnage has been taken as 4,700 tons for all the ships; the double bottom was considered available for fuel oil and the machinery space in each case is above 13 percent of the gross tonnage.

(14) The make-up feed water carried has been taken as 3 percent of the total steam consumption of the voyage, assuming that an evaporator is used to take care of any excess over 3 percent.

(15) Port fuel for the steamship and motorship with steam auxiliaries is 7 tons per day; and for the motorship with electric auxiliaries, 1 ton per day.

(16) Fuel oil for the steamship has been assumed at \$1.50 a barrel and 8 pounds per gallon (\$10 per ton); Diesel engine oil has been assumed at 4½ cents per gallon (\$1.88 per barrel) and 7.35 pounds per gallon (\$13.65 per ton).

(17) Lubricating oil at 75 cents per gallon has been allowed for as follows, which is the average practice in service: Geared turbine 1 gallon per 10,000 shaft horsepower hours. Reciprocating engine 1 gallon per 4,000 indicated horsepower hours.

Diesel engine 1 gallon per 3,000 shaft horsepower hours.

(18) Fresh water has been calculated at 50 cents per ton.

Table I shows the calculated data, assumed steam pressures, vacua, revolutions of propeller, boiler efficiency and machinery weights. The effective horsepower has been carefully calculated from Robertson's results and the propeller efficiency has been taken from Taylor's ρ^3 charts. The effective horsepower of the motorship was increased 40 horsepower to allow for the resistance of the struts. A hull efficiency of 1.05 was adopted for the single screw steamship and 1.00 for the twin screw motorship.

The calculated shaft horsepower has been increased by 20 percent to allow for the increase of power in service. The

TABLE I

	Motor ship No. 1	Steamship No. 2	Steamship No. 2
1. Type of machinery.....	{ 4 cycle Diesel	Geared turbine	Triple expansion Scotch
2. Type of boilers.....	Water tube	Water tube	Water tube

16a. Main engine steam consumption (pounds per I.H.P. per hour).....			14.40
17. Auxiliary steam consumption.....	25 percent	15 percent	
18. Total steam (pounds per S.H.P. per hour).....		13.9	
18a. Total steam (pounds per I.H.P. per hour).....			16.65
19. Total steam per hour (pounds).....		35,800	44,500
20. Boiler efficiency in service.....		70 percent	70 percent
21. Rate of combustion (pound per square foot heating surface).....		0.50	0.50
22. Calculated fuel (per S.H.P. per hour in service).....	0.42	1.19	1.52
22a. Calculated fuel (per I.H.P. per hour in service).....			1.37
23. Calculated fuel per hour in service (pounds).....	1,050	3,060	3,650
24. Weight of machinery (pound per S.H.P.).....	600	330	
24a. Weight of machinery (pound per I.H.P.).....			490
25. Total weight of machinery (tons).....	670	380	585
26. Make up feed water carried (3 percent) 5,000 miles (tons).....		240	300
27. Make-up feed water carried (3 percent) 10,000 miles (tons).....		480	600
28. Stores and provisions (5,000 miles) (tons).....	50	50	50
29. Stores and provisions (10,000 miles) (tons).....	100	100	100
30. Calculated fuel weight for 5,000 miles + 20 percent reserve (tons).....	280	820	975
31. Calculated fuel weight for 10,000 miles + 20 percent reserve (tons).....	560	1,640	1,950

efficiency ratio and boiler efficiency have been assumed to correspond to good service conditions and are naturally lower than trial and test results. The calorific value of the fuel oil for the steamships has been taken as 18,000 British thermal units per pound, which is a conservative value. The data used and results of the calculations for steam and fuel consumption are also given in Table I. Because of the large amount of fuel and make-up feed water carried on the 10,000 mile voyage the steamships will be unable to carry all of this in the double bottom and consequently will lose some cargo space. In fact, the ship would probably re-fuel during the voyage instead of carrying the entire fuel and water weight. The results, however, as worked up with all fuel and water are very valuable for comparative purposes.

The machinery weights include all engineering weights in engine and boiler rooms, shafting and propellers, and generating sets. The water in the boilers, engines and piping is included but make-up feed water is *not* included as a machinery weight.

The results of the comparison are tabulated in Table II for a voyage of 5,000 miles and in Table III for a voyage of 10,000 miles. The calculations for the geared turbine steamship for 5,000 mile voyage are given below to illustrate the procedure in obtaining the results tabulated in Tables I, II and III.

CALCULATIONS FOR STEAMSHIP WITH GEARED TURBINE

$$\text{Steam consumption} = \frac{2,545}{H_1 - H_2 \times \text{efficiency ratio}} = \frac{2,545}{369 \times 0.62}$$

11.12 pounds per S. H. P. hour.

$$\text{Total steam per hour} = 11.12 \times 1.25 \times 2,570 = 35,800 \text{ pounds.}$$

$$(H_1 - q_2) \times \text{steam per hour}$$

$$\text{Fuel per hour} = \frac{\text{B.t.u. per pound oil} \times \text{boiler efficiency}}{1,075 \times 35,800}$$

$$= 3,060 \text{ pounds per hour.}$$

$$\frac{18,000 \times 0.70}{3,060} = 1.19 \text{ pounds per S.H.P. per hour.}$$

$$\text{Weight of fuel carried per trip} = \frac{20.8 \times 24 \times 3,060}{2,240} \times 1.20 =$$

820 tons.

(An allowance of 20 percent reserve has been allowed for weight of fuel carried as indicated above.)

$$\text{Make-up feed water for geared turbine ship} = 20.8 \times 24 \times 35,800 \times 0.03$$

$$= 240 \text{ tons per trip.}$$

$$\text{Make-up feed water reciprocating engine ship} = 20.8 \times 24 \times 44,500 \times 0.03$$

$$= 300 \text{ tons per trip.}$$

$$3. \text{ Gross deadweight} = \text{displacement} - (\text{hull} + \text{machinery weights}) = 14,380 - (4,000 + 380) = 10,000 \text{ tons.}$$

$$4. \text{ Cargo deadweight} = \text{gross deadweight} - (\text{fuel} + \text{water} + \text{stores}) = 10,000 - (820 + 240 + 50) = 8,890 \text{ tons.}$$

$$9. \text{ Days on run} = \frac{5,000}{10.5 \times 24} \times 1.05 = 20.8 \text{ days.}$$

$$10. \text{ Days in port} = \frac{8,890 \times 2}{1,500} \times 1.10 = 13.0 \text{ days.}$$

$$12. \text{ Single trips per year} = \frac{365 - 30}{20.8 + 13} = 9.9 \text{ trips.}$$

$$15. \text{ Tons carried per year} = 8,890 \times 9.9 = 88,000 \text{ tons.}$$

$$21. \text{ Fuel used at sea per trip} = \frac{3,060 \times 20.8 \times 24}{2,240} \times 1.05 = 717 \text{ tons.}$$

$$\text{Fuel used in port per trip } 7 \times 13 = 91 \text{ tons.}$$

$$\text{Total fuel used per single trip } 717 + 91 = 808 \text{ tons.}$$

$$\text{Cost of fuel per year } 808 \times 9.9 \times \$10 = \$80,000.$$

$$22. \text{ Lubricating oil at 1 gallon per 10,000 shaft horsepower hours. } 2,570 \times 20.8 \times 24 \times 9.9$$

$$= 1,270 \text{ gallons per year.}$$

$$\text{Cost of lubricating oil at 75 cents per gallon} = \$950 \text{ per year}$$

Rate per ton cargo to give 10% return on investment.....	\$6.19	\$6.70	\$6.72	\$7.04	\$7.62	\$7.85

Cost of make-up feed water at 50 cents per ton (geared turbine ship)=240 × 9.9 × \$0.50 = \$1,190 per year.

22a. Lubricating oil for reciprocating engine ship.
1 gallon per 4,000 I.H.P. hours.
 $\frac{2,670 \times 20.8 \times 24 \times 10.1}{4,000} \times \$0.75 = \$2,520$ per year.

Cost of make-up feed water at 50 cents per ton =
 $300 \times 10.1 \times 0.50 = \$1,515$.

25. Port charges:

Pilotage (inward and outward).....	\$300
Towage (inward and outward)	200
Miscellaneous fees	100
Cooperage and dunnage	300
Clerks, watchmen, etc.	200
	\$1,100

• Dockage at 2 cents per ton per day = $4700 \times 13 \times 9.9 \times \$0.02$ = \$12,100

Tonnage dues (6 cents and 34 cents) = $4700 \times \$0.20 \times 99$ = 9,300

Miscellaneous fees listed above = 1100×9.9 = 10,900

Total port charges per year..... = \$32,300

27. Stevedoring of cargo = $88,000 \times 2 \times 0.70 = \$123,000$.

CALCULATIONS FOR MOTORSHIP (Electric Auxiliaries and Winches)

10. Days in port $\frac{9,380 \times 2}{1,500} \times 1.10 = 13.75$ days.

21. Fuel used at sea per trip = $\frac{1,050 \times 20.8 \times 24}{2,240} \times 1.05 = 246$ tons.

Fuel used in port $1 \times 13.75 = 13.75$ tons.
Total fuel per single trip = 260 tons.
Cost of fuel per year = $260 \times 9.7 \times \$13.65 = \$34,400$.

22. Lubricating oil at 1 gallon per 3,000 shaft horsepower hours
 $\frac{2,500 \times 20.8 \times 24 \times 9.7}{3,000} = 4,040$ gallons per year.

Cost of lubricating oil at 75 cents per gallon = \$3,040 per year.

21a. Fuel used by motorship with steam auxiliaries and winches and donkey boiler.
Additional fuel used at sea by steam auxiliaries (allowing 2 tons per day increase over electric auxiliaries) =
 $2 \times 20.8 \times \$10 \times 9.7 = \$4,000$ a year.
Increase in port fuel with steam winches
 $13.75 \times 6 \times \$10 \times 9.7 = \$8,000$.
Total fuel cost per year = $\$34,400 + \$12,000 = \$46,400$.

24. The wages of the crew are given below. The monthly wages for all the ships are kept the same. The motorships will have the same crew as the steamships with the exception of the firemen. There will, however, be electricians or additional motormen carried on a twin screw motorship and the wages of these additional men will practically balance the firemen of the steamships.

CREW'S MONTHLY WAGES (U. S. S. B. Scale, effective April, 1922).

Master	\$300	Second Assistant	\$145
First Officer	165	Third Assistant	130

			\$370

Total per year....=\$37,500

CONCLUSIONS

In order to make a definite comparison of the several ships, an item of profit (line 19) equal to 10 percent of the initial cost has been added as one of the capital charges. It is true that profit is not generally considered as one of the capital charges; yet it gives a convenient method for the analysis and allows the comparison to be based on freight rates per ton carried (line 29).

The results of the comparison for the 5,000 mile voyage, shown in the last line of Table II, indicate the following:

(1) The motorship with the all steam auxiliaries shows a gain of about 6 percent over the motorships with electric engine room and deck auxiliaries. Or for a freight rate of \$4.54 per ton the motorship with steam auxiliaries would pay a profit of 10 percent against 5.7 percent for the motorships with electric auxiliaries.

(2) A motorship with all steam auxiliaries, selling at \$10 a ton before converting, will give the same return on the investment as a geared turbine steamship selling at a price such that it can be put in service at an overall cost of \$25 per ton. The ship fitted with triple expansion engines and Scotch boilers must be worth less than \$25 a ton to operate on an equal basis. (Line 29, Table II, Column 4.)

(2a) A motorship (with all electric auxiliaries) selling at \$10 a ton will operate on the same basis as a geared turbine and watertube boiler ship worth about \$33 a ton. Allowing \$10 per ton for reconditioning the steamship, which is to be run with the original steam machinery, the ship should sell for \$23 per ton to pay the same profit as the motorship. The reciprocating engine ship will be on an equal basis at a service value of \$25 a ton or a selling price of about \$15 a ton.

(3) If the geared turbine ship is to sell "as is" for \$30 a deadweight ton and allowing \$10 a ton for refitting and repairs (total value \$40 a ton), the freight rate will be \$5.05 per ton carried (Column 7). For the motorship with electric auxiliaries to give a 10 percent return with this same freight rate the original cost before conversion would be \$18.50 per deadweight ton.

Present annual expenses (line 29, Table II, Column 7) = \$439,000

Increase capital charges at \$18.50 per ton (185,000

— 100,000) × 25 percent

21,000

New operating expenses

\$460,000

Rate when carrying 91,000 tons per year.....

\$5.05

(4) For the same conditions mentioned in (3) above the reciprocating engine ship should sell for a price such that it can be put in service at a cost of about \$30 per ton. (Column 6, Table II.)

(5) A comparison of lines 29 and 14 in Table II shows in general that for equal profits at the same freight rate, the value per ton deadweight for the geared turbine steamship

should be about half that of the motorship with all steam auxiliaries. The reciprocating engine ship should have a value of about one-third that of the motorship. If the comparison is made with the motorship with electric auxiliaries, the above ratios are about 1 : 2 and 1 : 2½.

As already pointed out this comparison is not intended to indicate that all geared turbine ships are always more economical than reciprocating engine ships. Table I shows clearly that the geared turbine installation is better not only because of the higher initial heat contents, lower vacuum and better efficiency ratio, but also because of the lighter weight of the watertube boilers. The two types of steamships may be considered, if desired, as representing a steamship with good economy and a steamship with poor economy, irrespective of the type of machinery and boilers installed.

While the foregoing analysis indicates that the converted motorship with all steam auxiliaries is superior to the motorship with all electric auxiliaries, it is very doubtful if this difference would be realized under actual working conditions covering a period of years. The repairs and depreciation on the steam auxiliaries would no doubt be higher than for the electric auxiliaries. Further, it may be that the fuel consumption allowed for the steam auxiliaries at sea is too low. By standardizing the sizes and power of the electric auxiliaries and Diesel generating sets the first cost may be appreciably lower than that used in the calculations. The all-electric auxiliary installation is by far the simplest and most satisfactory from an engineering standpoint and certainly deserves a very careful analysis based on more complete data than the writer had access to.

(6) On the 10,000 mile voyage (Table III) the results are in general similar to those for the 5,000 mile voyage except that the advantage of the motorship is even more marked. For instance, columns 11 and 12 (Table III) show practically identical freight rates (line 29) for a 10 percent profit, yet line 14 shows the total cost of the motorship per gross deadweight ton practically 2½ times that of the steamship. On the 5,000 mile voyage the ratio of costs was about 2 to 1 instead of 2½ to 1 shown here.

If the steamship (Column 14, Table III) sells for \$30 per ton + \$10 for the reconditioning (total value \$40 per gross deadweight ton), the ship for conversion to motorship with all electric auxiliaries could sell at \$31.20 and still pay the same profit as the steamship for a given freight rate. In other words, for a 10,000 mile voyage a ship could be purchased at the same price as the steamer to run "as is" and be converted to a motorship with all electric auxiliaries and make the same profit as the steamship!

Annual receipts from cargo at \$7.62 ton = $7.62 \times 55,200 = \$422,000$
Annual operating expenses, column 11, Table III..... = 369,000

Increase possible in capital charges..... = \$53,000

Total capital charges (\$53,000 + 150,000)..... = \$203,000

New value of ship

812,000

Conversion charge

500,000

Original value of ship (\$31.20 per ton).....

\$312,000

The results given in the tables are for a ship of 10,000 tons gross deadweight and a sea speed of 10½ knots but the results will have practically the same relative values for ships of 8,000 to 12,000 tons and speeds of 10 to 11 knots. Speeds much lower than 10 knots are too low for the best results in service and most of the cargo ships built during the war are hardly suitable for speeds greater than 11 knots.

Mr. John Anderson in his paper before the Institution of Naval Architects in 1918 has shown that ships of less than 8,000 tons are not suitable for long voyages, and the writer has shown in his article in the January issue of MARINE ENGINEERING AND SHIPPING AGE that the Diesel engine does not have any advantage over steam for short voyages. Hence it does not appear feasible to convert the smaller 5,000-ton ships built by the Submarine Boat Corporation into

motorships. However, only a comparative study of this size ship on a given trade route with both steam and Diesel machinery can decide the point definitely. A comparison of the data in Tables I, II and III shows that the motorship is more economical on the longer voyages where saving in the weight of fuel and water is a large item.

CUBIC SHIPS AND SHIPS NOT LOADED TO FULL CAPACITY

In studying the results presented in Tables II and III it should be distinctly borne in mind that they are worked up for ships with cargo weights equal to their full net deadweight capacity. A considerable portion of the advantage gained by the motorship is due to the increased deadweight carrying capacity brought about by the reduced weights of fuel and feed water. For cubic ships that carry cargoes occupying more than 50 cubic feet per ton and ships that are not loaded to the draft marks, the motorship cannot claim the advantages of increased deadweight capacity. Further, the space occupied by the machinery in the motorship will be no smaller than that occupied by geared turbines and watertube boilers; hence there is no gain for the motorship in cubic capacity on voyages under about 6,000 miles. On a voyage of 10,000 miles, however, there is a gain for the motorship in cubic space as the steamship cannot stow in the double bottom all the water and fuel oil for so long a voyage.

On the 10,000 mile voyage, if the ships are not loaded to the draft marks, the cargo deadweight for comparative purposes will be the same. Let us assume the cargo carried per voyage is 6,000 tons for each ship. The following table gives the data and results for such a case, assuming for convenience the same shaft horsepower and speed as before and using the ships from columns 11 and 13, Table III.

TABLE IV.—CUBIC SHIP (at about $\frac{2}{3}$ capacity).
10,000 Mile Voyage

	Motorship	Steamship
Days on run + 5 percent.....	41.6	41.6
Days in port + 10 percent.....	8.8	8.8
Days per voyage	50.4	50.4
Voyages per year	6.65	6.65
Initial cost of ship	\$600,000	\$300,000
Present value per gross deadweight ton capacity	\$61.80	\$30
Tons carried per year.....	40,000	40,000
ANNUAL EXPENSES		
Capital charges (Table III).....	\$150,000	\$87,000
Fuel used at sea and in port.....	45,500	100,500
Lubricating oil and fresh water.....	6,200	4,300
Wages of crew	37,500	37,500
Subsistence of crew	8,500	8,500
Portage dues and port charges.....	17,900	17,900
Brokerage and management	20,000	20,000
Maintenance	56,000	56,000
Annual operating expenses	\$341,600	\$331,700
Rate per ton to give 10 percent return on investment	\$8.50	\$8.30

The results in the above comparison are very interesting. The motorship, which with a full load could carry cargo at a rate 5 percent less than the steamship (columns 11 and 13, Table III), must charge a rate $2\frac{1}{2}$ percent higher than the steamship when working as a cubic ship or when not loaded to full capacity as a deadweight ship. (As already pointed out, the steamship will lose some cargo space on this extremely long voyage because all of the fuel and feed water cannot be stowed in the double bottom. This will reduce the above ratios slightly for a cubic ship.) In this comparison in Table IV neither the increased weight of the Diesel machinery nor the reduced weight of fuel and water have any influence except a slight effect on the displacement and shaft horsepower. The reduction in shaft horsepower due to difference in fuel-water weights is about 6 percent, which will reduce the operating expenses by less than 1 percent.

To appreciate the advantage of the motorship on the long

voyage with full cargoes, the cargoes carried per year should be compared (line 15, Tables II and III). On the 5,000 mile voyage the motorship carries 3,000 tons (3.4 percent) more cargo per year than the geared turbine and watertube boiler ship and 5,500 tons (6.4 percent) more than the reciprocating engine ship. On the 10,000 mile voyage (line 15, Table III) the increased carrying capacity of the motorship is 12.2 percent more than the watertube boiler ship and 17.4 percent more than the ship with Scotch boilers.

DIESEL-ELECTRIC DRIVE

If a Diesel electric installation is used, the weight of the installation will be slightly less than that for the ship with reciprocating engine and Scotch boilers, i.e., 470 pounds per shaft horsepower of the propelling motor. The fuel consumption in service will be between 0.46 and 0.50 pound per shaft horsepower of the propelling motor or about 10 percent higher than that of the direct connected Diesel installation. The space occupied by the machinery will be about the same as the direct Diesel installation and perhaps slightly greater. The net result will be about the same cargo deadweight as the motorship with direct connected Diesel engine. The cost of conversion is problematical. Due to the smaller engines and higher revolutions per minute used, the Diesel machinery will be considerably cheaper. If the electrical cost can be kept down, the Diesel-electric drive offers possibilities. However, for the cargo ship many of the excellent advantages of the Diesel-electric drive, such as ease of control, good economy at reduced speeds, etc., offer no special attractions.

TWO CYCLE ENGINES

The comparisons given above are for ships fitted with four cycle engines. If two cycle engines are used, the machinery weights will be reduced and the increase in fuel consumption will not be appreciably greater. Due to the smaller number of cylinders and reduced weight, the first cost of the main engines should be between 10 and 25 percent less than for the four cycle installation. The motorship with two cycle engines theoretically should be superior to the one with four cycle engines but probably more depends, in the present stage of development, on the particular make of engine rather than on the cycle.

The foregoing calculations are not intended to prove the superiority of any of the types discussed. An attempt has merely been made to present the problem that is attracting so much present day attention in as clear and fair a light as possible as a guide to shipowners who contemplate buying some of the war-time ships.

The writer is aware that his assumptions and data are not the same that everyone approaching the problem would use. There are so many possibilities for changing the assumptions and data here and there that no two could agree in all the details. Yet the broad conclusions reached are comparable and any changes can readily be made in the first cost, depreciation, insurance, etc., to investigate any special case.

Exports Drop: Imports Increase

THE quantity of our ocean-borne imports is steadily increasing and that of our out-bound commerce is as steadily falling off, according to a statement just issued by R. T. Merrill, director, Bureau of Research, United States Shipping Board. The Bureau, in making public the results for the calendar year 1922 and in comparing these results with those of 1921, makes the following comment:

The total export commerce of the United States, exclusive of that moved upon the Great Lakes, has in the last year decreased by 5,500,000 tons while the inward-bound business has increased almost 10,000,000 tons. The total commerce therefore of the United States has increased by over 4,000,000 tons.

Punishments of Merchant Seamen

Changes in Penalties for Crimes and Offenses—Existing Laws Which Affect the Discipline and Economy of a Ship

By Wendell Phillips Raine, M.A., LL.B.*

FROM the days of Jonah to the present time much has been written concerning merchant seamen, and everyone is familiar, through history and story, with the hardships and the horrors of the mariner's life and with the harsh punishments that would be meted out to him for the commission of crimes and offenses.

A hundred years of our own history showed surprisingly slight modification in the severity of statutory penalties and in the decisions concerning the masters' right to enforce discipline. The seamen were little better than slaves. The turning point in their emancipation dates from the passage of the White Act, December 21, 1898. Even as late as 1910, however, the Seamen's Union, in a petition to Congress, decried their unjust treatment. And today, although the Seamen's Act (March 4, 1915) went far towards removing the most gross injustices, there are many who believe that the punishments for certain offenses are still extraordinary and unjust.

It is the purpose of this paper to consider the changes in penalties and punishments since the first congressional statutes of 1790; to show to what extent they were little by little modified; and to present the existing law. It will not discuss such crimes as murder, rape and others of personal character but will confine itself to the following offenses—offenses which "affect the discipline and economy of the ship": (1) The destruction of the ship by arson or in any other way; (2) piracy; (3) mutiny; (4) damaging of the ship or its cargo or embezzlement of the cargo; (5) smuggling; (6) assault; (7) disobedience and negligence; (8) drunkenness; (9) desertion; (10) absence without leave; (11) quitting the ship on arrival at port.

The first three are of grave criminal nature, and are, therefore, the least unjust in the severity of their punishments. The next five in order are also felonious in character, though to a lesser degree, and they, too, will seem to necessitate punishment of a more severe nature than the last three offenses, which are questionably offenses at all, and the punishments for which have received the most severe condemnation. The advance made in the treatment of the first eight, although slow enough, is in line with the advance made in criminal law; but the penalties inflicted for desertion and its sister offenses, having no model and being peculiar to merchant seamen, show less change and are more objectionable.

EARLY CAPITAL OFFENSES

For the first three crimes—including arson, destruction of the ship, piracy, and mutiny—our first criminal law, April 30, 1790, provided the death penalty. Attempted piracy and attempted mutiny were punishable with three years' imprisonment and a fine not exceeding a thousand dollars. There was no relief in the severity of these punishments until 1835, when mutiny was removed from the list of capital offenses, and made punishable by 10 years' imprisonment at hard labor and a fine of two thousand dollars, and attempted revolt with imprisonment for five years or a fine of a thousand dollars or both. In fact, it is to be observed that attempted mutiny might receive even more drastic punishment than was provided for in the earlier statute.

There was little or no further change in these punishments until the passage of the Act of March 4, 1909—"an act to codify, revise, and amend the penal laws of the United States." Its most striking characteristic is the abolition of the death penalty for all types of crimes with which this paper deals, and the substitution of imprisonment and fines. A pirate is imprisoned for life, the most drastic penalty for the crimes under discussion. Likewise, arson, or the destruction of the ship by other means, no longer is punishable with death, but with a fine not to exceed five thousand dollars and imprisonment not to exceed 20 years. The punishments for mutiny and attempted mutiny are simply re-enactions of the provisions given above according to the Statute of 1835, the words "at hard labor" being omitted from the act of 1909.

GRAVE OFFENSES AGAINST THE SHIP

Among the next group of offenses—damaging of or embezzlement of the ship's cargo, smuggling, assault, disobedience or negligence, drunkenness, all offenses of a criminal character, both embezzlement and smuggling have been regarded, first by the general maritime law, and then by recent statutes, as among the grave offenses which a mariner can perpetrate against the ship. There has been not the slightest modification in the three statutes which deal with the subject. The Acts* of 1872, 1898, and 1915, all read in the same way, and are in line with the earlier court decisions.

For damaging the ship or its cargo or for the embezzlement of the cargo or any part of it, the seaman shall forfeit from his wages "a sum equal in amount to the loss thereby sustained," and also, at the discretion of the court shall be imprisoned for not more than 12 months. If a seaman is convicted of smuggling, "whereby loss or damage is occasioned to the master or owner, he shall be liable to pay such master or owner for such loss or damage; and the whole or any part of his wages may be retained in satisfaction or on account of such liability; and he shall also be liable to imprisonment for a period of not more than 12 months."

Assault, disobedience or negligence, drunkenness have particular interest because maritime law from its beginning has approved for them the application of corporal punishment by the master. The apparent need for the master to punish one who assaulted him or attempted to assault him early became one of the customs of the seas. The kind of corporal punishment inflicted varied with the seriousness of the offense and the character of the master. Yet the courts were likely to uphold the action of the master on the score of discipline.

Disobedience, without assault, or negligence of a gross kind had also been deemed offenses within the province of the master from the most remote period of maritime law. The master had supreme authority on board his vessel. He could inflict proper correction on his crew, both for past and present offenses; he had to have authority to enforce the discipline of the ship. Corporal punishment was the instrument best suited to accomplish that result. Flogging was usual. The readers of "Two Years Before the Mast" will remember

*Assistant professor of business law, University of Pennsylvania, Philadelphia, Pa.

*Shipping Commissioners' Act; the White Act; the Seamen's Act.

that horrible as flogging seemed to the author, he questioned the expediency of abolishing it. Only a few years after the publication of that book, however, Congress abolished such punishment. No doubt, it savored too much of the kind of thing the Northerner was denouncing in connection with slavery; and so, almost accidentally, and altogether incidentally, corporal punishment received its death blow. The circumstances are, perhaps, not generally known.

CORPORAL PUNISHMENT ABOLISHED

In the first session of the Thirty-first Congress, the advocates of the abolishment of flogging could get little attention. It looked as if the reform would not be accomplished. Finally, its upholders refused to support an admiralty bill arranging for the transportation of mails between various American and foreign ports, unless there were appended the following provisions: "That flogging in the navy and on board vessels of commerce, be, and the same is thereby, abolished from and after the passage of this act." (September 28, 1850.) Almost 50 years passed, however, before flogging and all kinds of corporal punishments were done away with by statute, and before there was, therefore, any provision for the punishment of a master who violated the law.

The earliest statute to deal specifically with these offenses, the Act of 1872, harsh as it will be seen to be in many ways, provided substitutes for corporal punishment. It meted out heavy penalties, choosing imprisonment as its instrument of punishment, but it did afford means for depriving the master of much of the summary justice he had been wont to inflict, and so marked a step in advance.

PENALTY FOR ASSAULT

In the case of assault the legislation of 1872 still stands, the later statutes of 1898 and 1915 re-enacting it word for word. The penalty for assault is still two years' imprisonment.

The Act of 1872 likewise made the first statutory provision for disobedience and neglect under two headings; wilful disobedience; continued wilful disobedience. For the former the seaman was subjected to not more than six months' imprisonment and a forfeiture of not more than four days' pay, the forfeiture of wages being at the discretion of the court. For the latter, the imprisonment was not to exceed six months, but was to involve either a forfeiture of 12 days' pay for every 24 hours of continued disobedience or neglect, or sufficient to defray any expense which had been properly incurred in hiring a substitute.

The Act of 1898 was a reversal and a modification of the earlier statute in that it made forfeiture of wages, for both wilful disobedience and continued wilful disobedience, the real penalty—the forfeiture of four days' pay for the former, and of 12 days' pay, or defraying of expenses, for the latter. Imprisonment was at the discretion of the court, but for only one month in the first instance, and for three in the second.

Whereas the Act of 1872 is important because it lessened the arbitrary power of the master, it was nevertheless harsh in its penalties, especially in its stress upon imprisonment in addition to fines and forfeitures. It is the Act of 1898 which reflected a fairer, a juster legislation. It deprived the master of the right to inflict punishment; but it did allow him to keep the culprit in irons, on bread and water, until a cessation of disobedience, or until the ship arrived in port, with full rations every fifth day. The Seamen's Act reaffirms all these provisions. It is no longer possible, then, for the master to inflict corporal punishment except for mutiny, and then only as a last resort. A seaman may be confined until he reaches port, but his actual punishment rests with the courts.

DRUNKENNESS

Drunkenness, in its results, was always recognized as a serious menace to the discipline of the ship. Other offenses,

already discussed, often were traceable to drunkenness, although the punishment inflicted was for the offense and not the cause. But the Act of 1872 regarded drunkenness as an offense in itself, not fully covered by other provisions, and made it a misdemeanor punishable with 12 months' imprisonment, if a seaman because of his drunkenness committed any act "tending to the immediate loss or destruction of, or serious damage to such vessel, or tending immediately to endanger the life or limb of any person belonging to or on board such vessel." The present Seamen's Act reaffirms this law.

There seems to be no reason for modifying the punishment for an offense that may be so serious in its effects. In general, however, as one reviews the trend of legislation for these first eight offenses one finds the trend towards alleviation and moderation. Capital and corporal punishment have disappeared; terms of imprisonment have in many instances been shortened; fines and forfeitures are the most usual punishments.

GREATEST EVILS REMOVED BY EXISTING LAW

There is not, as far as the writer can learn, any longer any serious quarrel on the part of the seaman regarding the recent laws for the crimes and offenses already discussed. The greatest evils have been removed. The seaman must admit the necessity for punishment of crimes and offenses that are crimes and offenses on land or sea. The existing penalties are not peculiar to the sea service. That they seem more flagrant because the seaman has promised in his contract not to commit them, does not mean, as far as the existing penalties are concerned, that the punishments are in consequence more severe. His contract merely emphasizes to him the necessity of conduct in accord with the discipline and economy of the ship.

While the mariner's contract is fundamentally the same in principle as any land contract, yet it presents some fundamental differences. First, the seaman can be made to complete his contract, whereas the ordinary contract merely permits the injured party to sue the injuring party for any damages he can prove he sustained. The mariner's contract is more like that type of land contract where equity courts will compel specific performance on the part of the delinquent—contracts, for example, for the sale of land or of chattels of a peculiar personal value, unobtainable elsewhere. Secondly, the mariners' contract is the only contract known to the common law in which the employer, by his own act, can directly inflict a punishment on the employed, for neglect of duty and breach of contract. These peculiarities of the mariners' contract, traceable in all their contracts from ancient times to the present day, are, of course, owing to the necessity of having the seaman bound absolutely to the ship for the period of his engagement, and of having him absolutely dependable during such service.

But the sailor regards himself to all intents and purposes a slave. Especially does he feel the shackles of slavery because he cannot desert, or leave the ship, or quit it in port, without being punished for so doing. His contention is that he is merely breaking his contract and that he is liable only to the extent of damages incurred. The master, on the other hand, may regard any one of these three defections as more detrimental to the discipline and economy of the ship than the actual offenses—violation of the moral law—for which he is punished not because he has violated his contract, although he has done that too, but because he has already committed a wrong.

DESERTION

The most serious offense he can commit, from the master's point of view, is desertion. Desertion is defined as the act by which a seaman deserts and abandons a ship or vessel in which he has engaged to perform a voyage, before the

expiration of his time, and without leave. It is more than a mere unauthorized absence from the ship without leave. It carries with it the intent not to return to the ship's service. Although there are circumstances that justify the leaving of the ship—*sickness, unwholesome food, cruel treatment, deviation in the route, unseaworthiness of the craft—in all cases the justification must be clearly shown, †and no slight pretext can be admitted, such as bad food on a certain day, or a possible leak, or the infliction of moderate chastisement because of the disobedience of orders.

The first Congressional Act (July 20, 1790) relating to the last three offenses of seamen—offenses not criminal in character—provided, in accord with the general maritime law, the following punishments for desertion: (1) The forfeiture of all the wages due the seaman, all the goods and chattels left on board ship, and the payment of damages if any such had been incurred by the master in hiring another mariner; or (2) his forcible apprehension by a justice of the peace at the request of the master. In other words, he paid an enormous penalty; or he was arrested and imprisoned until the vessel sailed.

The law remained practically unchanged until the Act of June 7, 1872. This was in no sense a modification of the Act of 1790, but rather an extension of it, and in general harsher in its penalties. It had, as has already been seen, an obsession for imprisonment as a punishment. The deserter was to suffer imprisonment for a period not exceeding three months, and in addition to forfeit his goods and chattels as well as the wages due him. He did not pay damages in addition to the above, but that was his only immunity, and the cost of such immunity was imprisonment. A backward step had been taken; the status of the seaman was worse than ever; and even though this act provided for commissioners that were to protect his interests, he continued to be punished for breaking his contract, and more severely punished at that.

The coastwise vessels received the first relief; in 1895††, seamen engaged in such traffic were exempted from the penalty of imprisonment. And in 1898, in the first act that frankly endeavored to better merchant marine conditions, seamen deserting in a home port did not suffer imprisonment. Finally, in the Act of March 4, 1915, imprisonment was abolished altogether as a penalty for desertion—a noteworthy advance after more than a century of seizures and imprisonment.

At present the deserter forfeits all or any part of the clothes or effects he leaves on board, and all or any part of the wages which he has earned. The greater justice of his present status is evident. He cannot be seized; he cannot be imprisoned. Yet the anomaly still remains that he is penalized for breaking his contract. Instead of paying damages, he forfeits his wages and his belongings, regardless as to whether the loss to the ship is greater or lesser than the amount forfeited. Perhaps, with the increase of available seamen, future legislation will allow him to collect his earned wages and to secure his personal effects, and will make him liable for damages alone. When that happens, desertion will no longer be listed among the offenses of merchant seamen and punished as such.

ABSENCE WITHOUT LEAVE

Second in gravity, to the master assembling his crew, is the failure of the seaman who has signed shipping articles to go aboard the ship, or his absenting himself without leave after he has already gone aboard. For the former, the Act of 1790 provided that the seamen's contract should state, in writing, precisely the day and hour on which he was to go

aboard his vessel, and stipulated that if he were tardy he was to forfeit one day's pay, and that if he failed to go aboard at all, so that the ship proceeded without him, he was to lose the money already advanced him, together with a sum equal to the amount of the money so advanced, this amount to be secured through any court, or before any justice of the peace in the United States having cognizance of such cases. For the latter—absenting himself without leave—he was fined three days' pay for each day he was away, provided he returned by the end of the second day, or within 48 hours, the sum to be deducted from his wages.

The harshness of this act was in no way relieved by the Act of June 7, 1872, any more than were the provisions for desertion. First of all, the two offenses, that of failure to join the ship and absence from the ship without leave, were included in the same provision, and were made punishable with one month's imprisonment. There was no escaping of the imprisonment. At the discretion of the court the seaman might also forfeit two days' pay, and for every 24 hours of absence, a sum not exceeding six days' pay, or an amount that would cover the expenses of hiring a substitute. The spirit of the Act of 1872 is the same whether it relates to desertion or absence from the ship. Severity of penalty to stop desertion and kindred offenses marks its every article. In short, the penalty made profit out of the seaman's breach of contract, and imprisoned him at the same time.

Relief came to the absentee seaman and to the seaman who failed to join his ship in 1898, as it did for the deserter. It distinguished between the offense in a (1) home port or in the domestic trade, and (2) foreign trade in a foreign port. For the first, imprisonment disappeared, and the seaman forfeited two days' pay, or an amount that would cover the expenses of hiring a substitute. If the offense occurred in a foreign port in the foreign trade, he might be imprisoned for a month, or forfeit two days' pay. The Seaman's Act (1915) did away with imprisonment altogether, retaining only the provision for the two days' pay, thus putting the seaman's contract in this respect very nearly in the class with any other type of contract.

When one breaks the terms of one's contract, one is liable to the injured party for whatever the injured party has suffered. Under the Seaman's Act, the remission of two days' pay seems a reasonable amount to regard as payment for damages; and it can very well be regarded as a payment for damages instead of a punishment for a criminal offense. It established a precedent which can be employed in the future in determining the penalties for the other offenses which are merely violations of the contract and not criminal in character.

Desertion and quitting the ship in the home port will have to receive similar treatment. For the last named offense, there was no legislation until the Act of 1872, which provided for the forfeiture of a month's pay, a law which has been reaffirmed and is incorporated in the Seaman's Act.

IMMEDIATE MODIFICATION OF EXISTING LAWS UNLIKELY

It is unlikely that there will be any immediate modification of the existing laws regarding the offenses of merchant seamen. No other country, excepting Australia, has granted so much to the mariner. As one surveys our whole shipping history, he realizes how much has been gained. Capital punishment has been abolished; corporal punishment has been abolished; seizure of a seaman is no longer possible; imprisonment terms have been reduced; and fines and forfeitures are now equitably adjusted to the actual loss incurred. Yet the seamen hope for more. Even admitting the necessity for punishment in the case of wilful disobedience, they regard the confinement in irons on bread and water as a form of punishment tyrannous and exceptional,

British Shipbuilding Outlook Much Brighter

Number of Laid-Up Vessels Continues to Decrease, British Idle Tonnage Has Been Reduced 45.7 Percent During Past Year

By W. H. Wendon

THE outlook for British shipbuilding, and that of allied industries, is brighter than at any time since the great slump set in. Shipowners in all quarters of the United Kingdom are taking their courage in their hands and are placing orders which will keep many yards busy for the remainder of the current year. Vessels of all types are included in this accretion of contracts, from the stately liner to the ubiquitous "tramp."

This happier frame of mind on the part of shipowners has come about only after protracted study of the world-wide shipping and trading situation. And in this regard the views of the experts differ widely as to the wisdom of giving out contracts for new tonnage. Indeed, in at least one notable instance, optimism and the placing of orders for new vessels certainly do *not* go hand in hand. Messrs. Furness, Withy and Company are to increase their fleet by four large Diesel-engined vessels, but as against this interesting fact, Sir Frederick Lewis, the chairman of the Furness, Withy Line, and whose experience in the shipping trade covers a vast field, is of the view that the trading outlook at the moment is difficult and uncertain, and that it must continue so until international trade can be encouraged and developed by an absence of political disturbances and some attempt made at stabilization of exchanges.

PIONEERS NEEDED

As has been the case for a long time past, what has been most needed in order to give the shipbuilding industry a fillip has been shipowner "pioneers," and more particularly is this the case in regard to Diesel ships, which, although increasing in numbers and in size, are still to many an unknown quantity. It is a case, speaking generally, of their not having been tried to ascertain if they are wanting. At least one prominent shipping man has been frank enough to admit the absence of this pioneering spirit in regard to Diesels, although at the same time his company has, in conjunction with an allied undertaking, shared a contract for a new boat with reciprocating engines. Sir Laurence Phillips, chairman of the Court Line, an old-established and well-managed cargo boat concern which has distributed 20 percent per annum to its shareholders of late years, is the authority to whom I am referring. He and his co-directors have considered the whole shipping situation, and have come to the decision that they would not be justified at the present moment in contracting for many new boats, but they think things are, by comparison, so much cheaper that they cannot hurt themselves by having a steamer, or at least a share in one.

SHARING THE RISK

So, as I have hinted, they are forming a subsidiary company—the United British Steamship Company, Limited—and have gone in with the Cressington Steamship Company, which is under the same management, and in this new company they have put up the capital between them. They have ordered a steamer which they think, in the long run, will make money; but the nice point arises: Have the directors got in "at the bottom?" This phase is uppermost in the minds of shipowners at the present time. Many feel that by refraining from contracting now, they will ere long be able to secure new tonnage a little—some say a lot—cheaper. At

all events, the Court Line, in their new venture, admit that it is quite possible that they have not got in at the bottom, but at any rate they have shared the risk, and they consider they have not much to lose. It is, perhaps, not a little singular that, while the company is thinking of new tonnage, even though it be on a small scale, the chairman cannot see that we have yet passed the worst; but, as bad times cannot be expected to go on for ever, he is apparently content to think and believe that good times will be restored some time in the future.

Reverting to Diesels, the Court Line directors, in fixing the type of vessel to be contracted for, considered whether they would build a vessel with Diesel engines, but they came to the conclusion that, while there were many advantages in this method of propulsion, they would rather, for the present, look on, until they could be certain from other people's experience that they were absolutely suitable to their type of vessel. In common with many other owners, however, they will watch carefully the development of internal combustion engines for marine purposes.

So much for the views of those who are inclined to pessimism. In far more hopeful frame of mind is Sir William Noble, an ex-president of the Chamber of Shipping of the United Kingdom, and a successful shipowner at that—who manages the well-known Cairn Line of Steamships, Limited. Much value is detracted from Sir William Noble's bright outlook, however, by the fact that, so far as I am able to learn, he is not backing up his opinion to the extent of contracting for new tonnage—at all events, not on a large scale. However, he sees in the present position qualifications which enable us to look to the future with hope, even if the present is enshrouded in gloom, that is, were there nothing to qualify the unequal balance between the amount of world tonnage and the volume of world trade.

INEFFICIENT AND OBSOLETE VESSELS ARE UNEMPLOYABLE AND UNSALABLE

The first of Sir William Noble's "qualifications" is that in the world's merchant fleet today there are many obsolete vessels, more than in ordinary times, owing to the Great War. Of vessels of over 25 years of age there were on a recent date no less than three and a half million tons, while there are probably two million tons more unaccounted for in Lloyd's classification. These vessels are inefficient and uneconomical, and can never expect to trade again. They will have to be scrapped and, in Sir William Noble's view, they should, in the interests of efficiency, be scrapped. My authority then deducts three and a half million tons as representing the tonnage of oil tankers, as these vessels do not come within the orbit of the ordinary freight market, and he asks: "Is it not proper to deduct a certain proportion of the American war-built fleet, which, though not old, is yet regarded as inefficient, and is now unemployable and unsalable?" He takes into consideration, also, the three million tons estimated to be included in this category, "and which the United States Shipping Board may have to wipe off." Finally, Sir William Noble reasons from the foregoing that we have a total of about twelve million tons which may be deducted from the world's excess of fifteen and three-quarter million tons, leaving an actual excess of effective world tons amounting to well under four million tons, and he concludes

that, once shipowners realize that the excess of effective world tonnage is reduced to this figure, they can take heart of grace again. Sir William Noble's deductions should inspire confidence in the minds of his fellow shipowners, many of whom would, however, feel further convinced were he to give a lead in the matter on behalf of his company.

REDUCTION IN LAID-UP TONNAGE

Confirmation of the brighter feeling in United Kingdom shipping circles taken as a whole is forthcoming from the statistics of laid-up British and foreign tonnage at the 36 principal ports of the United Kingdom. The tables, which are compiled by the Chamber of Shipping of the United Kingdom, and are, therefore, reliable, bring the position up to January 1, 1923, and reveal that, as compared with October last, there is a fall of 11.2 percent in the amount of laid-up tonnage, and since January 1, 1922, a decrease of no less than 45.7 percent. The total number of vessels laid up a year ago was 712, of 1,307,593 tons net. On October 1, 1922, there were 456 vessels of 824,624 tons and on January 1 this year 411 vessels of 732,198 tons. That such a vastly increased quantity of merchant shipping should now be finding employment—of, it is to be presumed, a remunerative nature—in comparison with twelve months ago lends weight to the feeling that better times are with us. With better times for shipowning, so must there be more work for shipbuilders—at all events, that is the lesson of the past.

WAGE ADJUSTMENTS HAVE INCREASED DEMAND FOR TONNAGE

Lower wages have been a factor of great importance in contracts which have lately been placed with United Kingdom shipbuilders. As is now a matter of history, the main point of controversy between shipbuilders and their men was as to whether the 26s. 6d. a week war bonus should be abolished. Negotiations with a view to its extinction proceeded for many months, notwithstanding that before the employers decided to withdraw the remaining ten shillings of the 26s. 6d. it was patent to all in the industry that the prevailing high costs of production were bringing the trade to a standstill. With a comparatively amicable wages adjustment, however, the industry was again set going and orders were distributed with refreshing frequency.

The extent of the increased demand for new tonnage is plainly discernible in official statistics recently compiled. Thus, 78 vessels of 231,187 tons gross were commenced in the quarter ending December 31 last, as against only 55,290 tons in the corresponding period of the previous year. A slight reduction took place in the first quarter of 1922, and a still lower level—38,877 tons—was reached in the succeeding quarter. The third quarter of the year, however, showed an increase of about 44,000 tons, while in the final three months the total reached up to within 30,000 tons of the tonnage placed in the water. While this is, of course, by no means "boom" time progress, it is, in all the circumstances, an encouraging feature. Furthermore, a fair proportion of the vessels contracted for since the revival set in would not have been commenced in time to be included in the figures which I have quoted, so that the position is to that extent better than appears on the surface.

TWO SHIPYARDS REOPEN

Two shipbuilding yards, each of which has been closed for many months, are to reopen. One belongs to the North of Ireland Shipbuilding Company, of Londonderry. The other is the River Clyde Shipbuilding Works at Whiteinch, Glasgow, which were owned by the Lloyd Royal Belge, of Antwerp. The Glasgow property has been acquired by the Australasian United Steam Navigation Company, Limited, of which Lord Inchcape, the head of the P. and O. Company, is chairman, and it is expected that the works will be reopened shortly and operated by a well-known firm on

the Clyde. A few years ago the yard turned out quite a large number of vessels for the Belgian steamship company by which it was owned, but, with the increased cost of production and difficulties owing to the Belgian rate of exchange, the yard was compelled to close down. The steamship company, incidentally, has also experienced hard times owing to the depression, and has, in fact, recently disposed of many of its large and newly-built steamers, at, of course, a mere fraction of the boom-time sums paid for them.

Status of Government Merchant Fleet

J. Barstow Smull, president of the United States Shipping Board Emergency Fleet Corporation, has made public the following status of the Government fleet:

ASSIGNMENT OF SHIPPING BOARD TONNAGE TO TRADES FOR THE MONTH ENDING DECEMBER 31, 1922

Trades	Number Vessels	D. W. T.	Percent
U. S. Government—			
Army Service	1	10,013	0.30

Concrete cargo tied up.....	2	6,078	
Vessels chartered to Independent Companies	10	35,031	
*Tankers	87	784,785	
Under custody of U. S. S. B. as mortgagee	2	16,621	
Awaiting orders of reconditioning.....	1	15,000	
Awaiting assignment	9	69,545	
Awaiting delivery to purchaser.....	1	5,610	
Contract cargo-unfinished (steel).....	1	9,400	
†Grand total.....	1,379	9,846,611	

*Includes 7 concrete tankers of 48,783 D. W. T.

†Does not include 6 Army transports of 38,235 D. W. T., title to which is vested in Board, although physical delivery to Board has not been effected.

Punishments of Merchant Seamen

(Continued from page 144)

though preferable to the corporal punishment for which it was substituted. A still worse form of slavery exists, they contend, as regards the penalties for desertion. Unlike other workmen, they are deprived of wages which they have already earned, not because of any criminal offense but because they have broken their contract.

To be forced by a criminal prosecution to fulfill their contract is the present grievance of the merchant seaman. They will regard themselves as really emancipated only when the three so-called offenses of desertion, absence without leave, and quitting the ship at the home port are deemed no longer offenses, but simply violations of a contract.

Recent Developments in Marine Insurance

**New War Risk Demand—Shipping Board Boats Re-rated—
Scuttlers and Mortgagees—New Syndicate Agreement—Abso-
lute and Constructive Total Losses—Average Settlements**

By "Bordereaux"

ONCE again the voice of the war risk insurer is heard in the land. The dread possibilities of France in the Ruhr, and the delicacy of the Near East situation with the war-loving Turk glooming in his tent, have had their effects upon shipping psychology. There is a renewed market for war risk insurance, and a very respectable volume of it is being written under open policies. Apprehension is felt in America for goods ashore in Germany; and especially by the American underwriter, because much of it has been covered in this market against strikes and civil commotion—and what is more likely than these kinds of disturbances in event of an uprising against the present German Government? London has shared in the war risk revival. She had to first go through her usual pow-wows between the companies and Lloyd's, to hammer out an agreement; after which concerted action prevailed. The Free of Capture and Seizure clause and the Strikes, Riots, and Civil Commotions clause were reinstated in all policies on all interests to or from or in or through Germany (exclusive of the occupied territory), and on all interests in German bottoms for whatever voyage. These risks excluded by the F. C. S. and the S. R. C. C. clauses are held covered subject to forty-eight hours' notice for cancellation at a premium to be arranged. The American rate is practically the same as the British rate, with the exception that our quotations are for "waterborne only," while theirs includes ten days on shore. The Institute of London companies' war rates are as follows: "To or from German ports, on German steamers, bound out, ten shillings; bound homewards, fifteen shillings. On other steamers, bound out, two shillings and sixpence; bound homewards, five shillings. Outward voyages carry a ten days' sailing warranty."

The Scuttler and the Mortgagee

MUCH has been written about the status of the innocent mortgagees in maritime transactions, and the matter appears to be by way of a drastic settlement in England where underwriters have more than once paid the penalty of sympathy with the man who loaned money on a ship that was later sent to the bottom with the connivance of its owner and master. The courts are always dodging the issue, in that they do not come out with a clean-cut decision pronouncing scuttling or casting-away a peril that was not insured against. Unless British underwriters get a clear court ruling on the subject they will very likely draft a clause of inclusion in all policies on mortgaged steamers excluding payment of losses caused by deliberate scuttling or casting away. It is admittedly a hardship to withdraw insurance protection from innocent third parties, such as mortgagees, who frequently be, but still it is felt to be imperative that the principle be established that in no instance whatever shall an underwriter be called upon to pay a loss on a vessel which has been fraudulently cast away with the privity of the owner. Even if the law remains unaltered it is regarded as impolitic to continue to cover innocent mortgagees, as to do so would be to encourage mortgagees to take risks in advancing money to persons of doubtful integrity, since they could be assured of protection in event of fraudulent loss. In two important cases the English Court of Appeals

recently sustained the underwriters' appeals, in instances of this kind, but the ground of scuttling not being a peril insured against was not established. One of these, the *Grigorios* case, was won on the point that the warranty concerning the amount of insurance on disbursements had been broken. The other, the *Joanna* case, went the underwriters' way because the mortgagees were shown to have had no independent interest in the insurance.

Additional Shipping Board Re-ratings

TWO more shipping lines have been recommended to underwriters for improved cargo ratings by the Conference Committee whose report of October 20 last was at the time believed by many to be final. These additions have just been made:

(1) That the Cosmopolitan Shipping Company, operating out of New York to Havre, Dunkirk, Bordeaux and St. Nazaire, in so far as tonnaged by approved United States Shipping Board steamers, be granted the same classification as any of the following competing lines: Roosevelt Steamship Company; Sir W. Reardon Smith & Sons, Ltd.; Lloyd Royal Belge.

(2) That Swayne & Hoyt, Inc., operating out of Pacific ports of the United States to East Coast of South America, via Panama Canal, in so far as tonnaged by approved United States Shipping Board twin screw passenger steamers not over twenty years of age, be granted the same classification as the twin screw passenger steamers not over twenty years of age operated by any of the following competing lines: Nippon Yusen Kaisha; Osaka Shosen Kaisha; Toyo Kisen Kaisha; and that in so far as tonnaged by other approved United States Shipping Board owned steamers it be granted the same classification as similar steamers of the same competing lines.

NOTE: As it is contemplated by the Shipping Board to tonnage this line with passenger steamers, the service should be distinguished from other services tonnaged by cargo steamers only.

Marine Syndicates' New Agreement

THERE went into effect at the beginning of the present year a further amendatory and supplemental agreement between the United States Shipping Board, the Emergency Fleet Corporation and the subscribers to Syndicate A of the American Marine Insurance Syndicates. Under the provisions of the original agreement, entered into on June 28, 1920, the two former parties were required to appropriate the sum of \$1,000,000 as a working fund from which payments might be made to the Board of Managers of Syndicate A subscribers from time to time in installments as the Board might certify to be required, and in addition to make quarterly advances in the amount of \$250,000 each on account of the operating expenses of Syndicate A. The Shipping Board has advanced \$500,000 of this amount, but not the quarterly advances because the Syndicate managers did not need them. By the agreement the unexpended balance of the \$500,000 is to be returned to the Board not later than December 31, 1923. When the United States Salvage Association was organized the agreement was amended, effec-

tive as of July 1, 1920, permitting the subscribers to employ the Salvage Association to perform the services stipulated to be rendered by Syndicate A. In the prevailing depressed condition of shipping and commerce advances in the amounts originally provided for are not now needed for the operation of Syndicate A; hence the new agreement.

Under the new arrangement a balance of \$125,000 of the \$500,000 already paid in is to be retained by Syndicate A subscribers as an operating or "revolving fund." A plan of monthly settlements has been arranged, the subscribers rendering to the Shipping Board or Emergency Fleet Corporation bills, on the last day of each month, for services performed during such month, itemized so as to show the charge made for the account of each vessel. The work so done is understood to be at cost, so that there shall be no profit nor loss to the Syndicate A subscribers or the United States Salvage Association. These bills are to be paid by the Board or Corporation within thirty days from receipt thereof. These service expenses are to be paid out of the revolving fund, which the Board or Corporation bind themselves to repay so as to keep the fund at \$125,000.

Norwegian Mine Clause Canceled

NORWAY discontinued writing war insurance at the beginning of the year, and the Central Union of Norwegian Marine Insurers, as a consequence, declined to include after that date its eventual mine risk clause in ordinary hull policies. With the restrictions created by the Norwegian marine insurance plan of 1907 the liability of the marine underwriter included the consequences of risks caused by mines laid during the great war of 1914-1918. It is now up to the underwriter to prove that the loss eventually is caused by mines not laid during the great war. Unless special agreement is made at the inception of each individual voyage, the underwriter cannot be held for such mine risks, if the vessel journeys to Russian ports in the Black Sea, the White Sea, or seas affected by a new war or new preparations for war. Underwriters admit that mines have always been supposed to become harmless after floating for a year or two, and yet the Germans appear to have built mines that remain as dangerous as ever long after they should, theoretically, have gone dead. Even today, a mine is picked up, or run into with disastrous results, every once in a while. It is a risk worth insuring against.

Absolute and Constructive Total Loss

THE distinction between these two classes of losses would appear to be sufficiently self-evident, and yet confusion sometimes remains in the minds of the assured. Abandonment is a privilege of the assured, not an obligation. If he does not wish to do so, he cannot be compelled to abandon his property. When a vessel has been destroyed by fire or the sea or any other peril insured against there is an absolute total loss. Charred fragments may remain, or the ship's equipment may have survived, but the subject of the insurance has ceased to exist, and the underwriter, on proof of the loss and of the assured's insurable interest, must pay the face of the policy upon the production of that document; thereafter he is entitled to realize what he may out of the ruins. Should a ship sink in water too deep for salvage operations, or should she be captured by a belligerent in time of war and be condemned by a prize court, or where, owing to the loss of the vessel, the surviving cargo becomes short of destination and so located as to make forwarding impossible, then the thing insured, or a part of it may still exist but it is either definitely removed out of the possession of its owner and he is without chance of recovering it, or, while the goods may exist, the commercial adventure has been completely destroyed. If the cause of the loss was cov-

ered by the policy, then the underwriter must pay as for an absolute total loss.

Constructive total loss arises where the destruction of the property or the commercial adventure is not actual but probable. The ship may be fast on the rocks or on shore and her destruction appear highly probable; she may have sunk in fairly shallow water so that there is a possibility but not a certainty of floating her; she may have been captured by a belligerent, but a chance of restoration may remain, either by recapture or because the prize court finds her detention to have been invalid; or goods may have been saved from a wrecked vessel and be lying at a point where the possibility of their being conveyed to destination remains problematical—in all such instances the cases are of potential total loss. The assured then has the option of abandoning to his underwriters, if the cause of loss is covered by the insurance, he may serve such notice and claim as for a constructive total loss. The notice may be verbal or in writing, and must be given at once, or the right to abandon passes.

Mariners' Insurance Law for Japan

THE next session of the Japanese Diet is to have submitted to it by the Japanese Department of Communications a mariners' insurance law. Private companies have, in the past, looked after this interest, and there has been no national legislation on the subject. But this method has been found to be unsatisfactory because lacking in unity; furthermore, there are a number of shipowners over there who make no provision for insurance. With the recent establishment of a Social Board all business affecting laborers' insurance was transferred from the Department to the Board. After consultations between these two bodies the decision was reached to introduce the new measure at the Diet's next session.

Fruit Damage by Delay

THE United States Circuit Court of Appeals, Fourth Circuit, has recently held that where through negligent stranding a ship chartered for carriage of fruit was late in arriving at loading ports, with the result that fruit awaiting shipment deteriorated, but such as was though fit was loaded, the ship can be held liable for the loss through further deterioration on the voyage. See 284 Fed. Rep. 1. In this instance the cargo was bananas. The custom is to cut the fruit forty-eight hours in advance of the arrival of the ship, but because the vessel was delayed four days in arriving a claim for \$23,533.85 was made. The ship was late because she had stranded in consequence of gross negligence on the part of her navigators.

General Average at Destination

ONE of the propositions that is in for a heated debate when the International Chamber of Commerce meets at Rome on March 18-24 is as to whether general average settlements should take place at the port of destination instead of at the port of embarkation. American marine underwriters are a unit in opposing this eleventh-hour proposal. Indeed, they had no idea that such a subject was to come up, until the tentative program of the meeting was distributed. The Board of Underwriters of New York has unanimously disapproved the idea and has appointed a special committee to bring their views to the attention of the American delegates. They feel that as the parties most interested they should have been consulted in advance. Their opposition is based upon the ground that most ports of destination are without competent adjusters and, further, are not likely to have proper established laws and customs as respects general average.

Steamship Haleakala, Built by Sun Shipbuilding Company for Inter-Island Steam Navigation Company, Ltd.

Express Passenger and Freight Steamship Haleakala

Particularly Adapted to Tourist Trade Having Special Facilities for Handling Automobiles and Carrying Riding Horses

DESIGNED for tropical service between Honolulu and Hilo, the express passenger steamship *Haleakala*, recently completed at the Sun Shipbuilding Company, Chester, Pa., under the direction of Captain L. Curtis, for the Inter-Island Steam Navigation Company, Ltd., has many interesting features. The vessel is particularly adapted to the tourist trade. Every stateroom opens directly onto an open deck, assuring plenty of fresh air which is essential for comfort in a tropical climate. As the vessel will operate entirely in the tropics no steam heating system will be fitted but temporary provision for electric heaters in the crew's quarters have been provided. Another feature that will be appreciated by tourists is the 'tween-deck space which is specially designed for carrying automobiles.

The vessel has been built to the highest class of the American Bureau of Shipping. She has a speed of $17\frac{1}{2}$ knots or approximately that of such Atlantic liners as the *George Washington*, *America* and *Caronia*. The hull is subdivided by seven transverse watertight bulkheads all extending to the second deck except the collision bulkhead which extends to the upper deck. She is equipped with eight lifeboats, each having a capacity of fifty persons and surf boats, 11 of which are operated by Steward mechanical davits.

GENERAL DESCRIPTION

The *Haleakala* is a single screw steel steamship of the flush deck type, with raised forecastle. She is built on the transverse framing system and has a straight stem slightly flared forward. Her bows are flared and her stern is elliptical. The double bottom extends the entire length of the vessel and she has two complete hull decks and two superstructure decks.

There are two steel pole masts with wood pole topmasts. Each mast is built in two strakes with lap seams and strapped joints. Two steel cargo booms of 5-ton capacity, having

sufficient length to land loads 12 feet clear of the ship's side with derrick at about 45 degrees, are fitted on the foremast.

THE BOAT DECK

The deck houses on the boat deck are of wood. In the forward deck house on this deck are located the pilot house, wireless room and officers' quarters. On top of the pilot house is the flying bridge, the forward end and wings of which are entirely enclosed and fitted with windows. A standard compass, steering wheel, telegraph and telephones are installed on this bridge.

The usual standard navigating instruments and steering apparatus are located in the pilot house but, in addition to this, it will be noted from the plans that a chart table is installed in this room instead of in a separate chart room. The wireless room is made sound proof by hair felt fitted between the outer and inner sheathing. The after deck house is entirely devoted to passenger accommodations.

BRIDGE DECK

The forward portion of this deck or forecastle is arranged for handling the anchors, mooring lines and the cargo. The deck houses are of wood. It will be noticed that all staterooms are outside rooms and that all of their doors open directly on to the deck. These doors, which are particularly wide, all open forward and are fitted with stops and springs to prevent shocks. Windows in all staterooms and officers' quarters are of the balanced drop type with inside slatted blinds. The writing room forward is furnished in Colonial style and the smoking room aft is paneled in oak.

UPPER DECK

The crew's space is located at the extreme forward end of this deck, thirty seamen being berthed in one room and the

Deck Plan of New Express Steamship Haleakala

petty officers in separate staterooms. Between the crew's space and the passenger accommodations and in way of the main cargo hatch, stalls have been fitted for twelve horses. A baggage room has also been constructed just aft of the hatch and extending to a bulkhead which forms the after end of the inclosed portion of this deck.

The passenger accommodations on this deck are inclosed in steel deck houses, the sides of which are located far enough inboard from the bulwarks to provide plenty of promenading space.

SUITES DE LUXE

There are six suites with separate toilets and showers on this deck all decorated in different designs. A Pullman berth is fitted in each suite to accommodate a third person when desired. The remainder of the deck is occupied by first class accommodations, including a large social hall.

THE SECOND DECK

The forward end of this deck will be used for cargo space and for stowing automobiles. Cargo doors are fitted in the sides of the ship through which cars may be driven or merchandise trucked on or off. A feature here is a freight elevator on which several truck loads of cargo may be lowered to the hold at the same time and then wheeled to their stowage location. It will be noted from the plans that the only means of access for the horses on the deck above is through the cargo hatch, which means that they will have to be picked up by slings or driven up a ramp.

The first class dining saloon located just forward of the boiler hatch on this deck will accommodate 134 passengers at one sitting. It is finished in Colonial design and with tables seating six persons.

Aft of the dining room and along both sides of the engine and boiler casings are located the galley, pantry, bakery, linen room, engineer officers' quarters and crew's messroom. The cold storage rooms and steerage accommodations for women are located aft.

VENTILATION

Particular care has been taken to provide ample ventilation. In addition to the natural ventilation through cowls, fans are installed as follows:

A 400-cubic foot suction fan located in a locker on the upper deck drawing from the suite toilets and discharging to the atmosphere through a ventilator on the flying bridge.

Two 1,500-cubic foot fans located in the social hall entrance, taking air directly from the atmosphere and dis-

charging through ducts to each side of the dining saloon.

Two 1,300-cubic foot fans located on the upper deck level in the galley trunk taking air directly from the passageway on the upper deck and discharging through ducts to all rooms between frames 62 and 86 on the second deck.

Two 1,300-cubic foot fans located in the chief engineer's toilet and linen room on the upper deck, taking air direct from the passageway and discharging through ducts to all toilets and quarters between frames 29 and 62 on the second deck.

Two 1,300-cubic foot fans located on the upper deck entrance taking air direct from the atmosphere and discharging through ducts to the third class quarters.

Four 1,000-cubic foot fans will circulate air through a 10-inch air passage or cofferdam fitted around the engine and boiler casings in the way of the quarters. An individual 10-inch electric fan is fitted in each first class stateroom and special fans in the public rooms.

PROPELLING MACHINERY

The propelling machinery consists of one four cylinder triple expansion engine to be supplied with steam at 210 pounds per square inch at the throttle.

BOILERS

The vessel has four Babcock & Wilcox marine watertube boilers, each having 4,809 square feet of heating surface, or a total for the four boilers of 19,236 square feet, arranged for oil fuel. The boilers are thirty sections wide, each section having six and one-half clusters of four 2-inch tubes with one 4-inch tube over the furnace, the tubes being 10 feet

long. The boiler capacity has been so designed that three boilers will at all times maintain power with main engines and auxiliaries working maximum capacity, leaving one boiler for reserve, as required by the owners.

Each boiler is equipped with six Babcock & Wilcox mechanical atomizing oil burners, Cuyama type, arranged to operate under forced draft. Individual blowers situated at the rear of the boilers deliver the necessary air through ducts running under the boilers to the duct surrounding the burners formed by the outer and inner front plates of the boilers.

OIL AND BALLAST SYSTEM

The double bottom compartments, except under the engine and fire rooms and fore-and-aft peak tanks, are fitted for both oil and water ballast. The double bottom compartment under the engine room is for fresh water only and that under the fire room for oil only. The forepeak tank is fitted for water ballast only and the after peak tank for fresh water and ballast.

The oil system manifolds are located in the machinery space and are connected to the fuel oil transfer pump. There is a port manifold and a starboard manifold with separate suction pipes to each compartment and the piping is so arranged that oil can be transferred from a forward port tank to a starboard forward tank or vice versa for trimming purposes.

The ballast system consists of a starboard and a port manifold connected to ballast pump. Separate suction pipes run to each compartment and the piping is so arranged that ballast can be pumped to port or starboard and also to peak tanks.

Express Steamers Ordered for Eastern Steamship Line

Contract for Two Oil Burning, Turbine Driven, 17-Knot Passenger Steamers Awarded to Bethlehem Shipbuilding Corporation, Ltd.

A CONTRACT for the construction of two 17-knot, turbine driven, passenger steamers for night service on the Boston-New York run, operating through the Cape Cod Canal, was awarded last month to the Sparrows Point yard of the Bethlehem Shipbuilding Corporation, Ltd., by the Eastern Steamship Line, of which Calvin Austin, India Wharf, Boston, Mass., is president. The vessels, which were designed by Theodore Ferris, naval architect and marine engineer, 30 Church street, New York, will cost approximately \$3,650,000. The first vessel will be delivered in April and the second in May, 1924.

The principal dimensions of the vessels are as follows:

PRINCIPAL DIMENSIONS

Length over guards	402 feet
Length over hull	401 feet 1 inch
Length on 15-foot waterline	396 feet 4 inches
Length between perpendiculars	385 feet
Beam over guards	72 feet 6 inches
Beam over hull	71 feet 2 inches
Beam at 16-foot 6-inch waterline	56 feet 6 inches
Depth molded to main deck at side	23 feet 9 inches
Designed load draft	16 feet 6 inches

At the 16-foot 6-inch molded draft in sea water the vessels will have a displacement of 5,300 tons. The block coefficient on the displacement length of 395 feet is 0.5035.

Propulsion of the vessels will be by twin screws, driven by geared turbines. With the propellers turning at 120 revolutions per minute the designed shaft horsepower of the propelling machinery will total 6,400; at a 17-knot service speed

on a 16-foot 6-inch draft the estimated effective horsepower is 2,580 and at a 19-knot maximum speed on the same draft the estimated effective horsepower is 3,980.

It is estimated that the shaft horsepower required for a service speed of about 16½ knots will be about 4,500 and the fuel consumption for all purposes 1.2 pounds per shaft horsepower per hour. The fuel requirements will be as follows: 15 hour run, one way, 36 tons of oil; 15 hour run, round trip, 72 tons of oil; port use, 5 tons of oil; total fuel oil, round trip, 77 tons of oil, or about 530 barrels. The total fuel oil capacity in the deep tanks is 270 tons, which is sufficient for about three round trips.

The tonnage of the vessel is approximately: gross, 5,100; net, 2,850.

While the service speed of these steamers as night boats between New York and Boston operating through the Cape Cod Canal will be nominally 17 knots, because of delays and detentions on this route, such as fog, congested waterway through the canal, etc., and the possibility at times of operating outside Cape Cod, the steamers are designed to have a possible speed under maximum power, oil burning, of 19 knots.

WEIGHTS

The carrying capacity in service figures out as follows:

Equipped weight, water in boilers, condenser and piping	4,200 tons
Margin weight for equipped ship	250 tons
Fuel oil (bunker weight)	120 tons
Boiler feed water	70 tons

Culinary water	100 tons
Passengers and their effects	60 tons
Baggage, automobiles, etc.	20 tons
Provisions and stores	20 tons
Crew and their effects	10 tons
Cargo freight	400 tons
Trimming water	50 tons
Total.....	5,300 tons

The displacement on a 16-foot 6-inch draft will be 5,300 tons.

PASSENGERS AND ROOMS

The vessels are designed to carry but one grade of passengers in rooms while separate open spaces will be provided for berth travel of men and women. The total number of regular passenger rooms is 267; number of passengers with two in each room, 534; de luxe rooms with adjoining baths, 14; capacity, with two persons in each, 28; special rooms with adjoining toilet, 64; capacity, with two persons in each, 128. Total number of rooms, 345; total passengers in rooms, 690.

In addition to the stateroom accommodations provision will be made for berth travel for 160 men and 50 women, making the total number of berth travel passengers 210 and the total number of passengers 900. The crew will number, deck department, 46; engine department, 27; steward's department, 95; total crew, 168; total persons on board, 1,068.

These steamers will be equipped with lifeboats in davits with collapsible boats stowed underneath, life rafts not being considered desirable. The lifeboat equipment as designed will consist of four metallic lifeboats, 24 feet by 7 feet by 3 feet with a capacity of 30 persons each, giving a total capacity of 120; 12 metallic lifeboats, 26 feet by 7 feet by 9 feet by 3 feet 4½ inches with a capacity of 40 persons each, providing for a total of 480 persons; 12 collapsible lifeboats, 24 feet by 7 feet by 2 feet with a capacity of 40 persons each, providing for a total of 480 persons. This equipment provides a total boat capacity of 1,080 persons.

GENERAL ARRANGEMENT

The vessels will be twin screw steel sponson sided type passenger steamers with freight space on the main deck and one freight hold. The hulls will be constructed with transverse framing with web frames in conjunction with side stringers. A complete double bottom will extend fore and aft with tanks fitted for water ballast for trimming purposes, fresh water for ship's use and for boiler feed use. There will also be built-in tanks for culinary water and built-in deep fuel oil tanks. The fore and after peaks will be fitted for salt water trimming tanks.

The hull will be divided transversely by seven watertight bulkheads carried up to the main deck, stepped as required and fitted with watertight flats as shown on the plans. There will be one common shaft tunnel with port and starboard tunnel recess.

In view of their service through the Cape Cod Canal, and, due to the possibility of their taking a bad shear and fetching up with their bilges on the banks of the canal, the steamers will be provided with bilge protection through the midship portion of the hull made up of deep fuel tanks abreast the boilers, dry tanks in way of the engine room and cargo double bottom tanks up the sides in Nos. 2 and 3 holds with a longitudinal bulkhead port and starboard in way of the shaft tunnel.

The vessels will be fitted with two light steel masts for wireless and signalling apparatus, one main double smokestack and one ventilating stack, a duplicate of the main smokestack in appearance. The stem will be straight with a slight rake forward. At the saloon deck aft of the stem for about 48 feet light steel bulwarks will be fitted on each side. The stern will be of special type, elliptical in shape

around the guard line with waterline extension over the rudder. The vessels will be fitted with steel guards.

The general arrangement of the accommodations is shown on the plans. The vessels will be equipped with electric light and steam heat throughout.

There will be three freight doors on each side off of the main deck and a freight hatch forward through the main and lower decks to serve the forward freight hold. This hatch will be equipped with an elevator of 4,000 pound lifting capacity running from the tank top to the main deck level operated by an electric winch on the main deck. An elevator of 1,000 pounds lifting capacity will be installed on the port side of the after end of the freight deck for handling stores down to the galley and store room.

At the after end of the engine room on the level of the lower deck will be the ice machine room on the port side and the dynamo room on the starboard side.

PROPELLING MACHINERY

The propelling machinery will consist of two Parsons single reduction gear steam turbines and six cylindrical return tubular Scotch boilers, 16 feet 4 inches inside diameter by 11 feet 8 inches long over top heads, built for a working pressure of 200 pounds per square inch, and one donkey boiler vertical wet uptake type 6 feet inside diameter by about 101 inches high built for 150 pounds per square inch working pressure.

The twin screw turbine propelling machinery will be built from designs as furnished by the Parsons Steam Turbine Company, Ltd., of Wallsend-on-Tyne, in which each set will consist of one high pressure and one low pressure turbine in series each driving a separate pinion through single reduction gearing. Astern turbines of the impulse type capable of developing 60 percent of full ahead power will be incorporated in each low pressure ahead turbine. The revolution of turbines at full power ahead will be high pressure turbine, 1,920 revolutions per minute; low pressure turbine, 1,920 revolutions per minute. At these revolutions the turbines will develop a total of not less than 6,400 shaft horsepower. The speed of the propellers will be 120 revolutions per minute.

The six boilers will be arranged for two fire rooms with grates fore and aft and will be fitted with the Howden system of heated forced draft with heater tubes for raising the temperature of the air before it enters the furnace. The boilers will be connected to one smokestack.

The propellers will be solid right and left hand propellers of manganese bronze three bladed about 13 feet 9 inches diameter.

There will be two main surface condensers each containing 4,800 square feet of cooling surface.

PUMPS

The pumps will be of the Blake-Worthington type of the following dimensions:

- Two main circulating pumps about 14 inches diameter.
- Two main twin beam air pumps, 12 inches by 28 inches by 18 inches.
- Two vertical simplex feed pumps, 18½ inches by 13½ inches by 24 inches.
- One vertical duplex ballast pump, 10 inches by 12 inches by 12 inches.
- One vertical duplex fire and bilge pump, 12 inches by 8½ inches by 12 inches.
- One vertical duplex sanitary pump, 10 inches by 12 inches by 12 inches.
- One vertical duplex fresh water pump, 6 inches by 4 inches by 6 inches.
- One vertical duplex ice machine circulating pump, 6 inches by 4 inches by 6 inches.
- One vertical duplex scuttle butt circulating pump, 6 inches by 4 inches by 6 inches.
- Two vertical duplex brine circulating pumps, 7½ inches by 5 inches by 6 inches.
- One vertical simplex donkey boiler feed pump, 4½ inches by 2¾ inches by 6 inches.
- Two vertical duplex fuel oil service pumps, 7½ inches by 5 inches by 6 inches.
- One vertical duplex fuel oil transfer pump, 7½ inches by 9 inches by 10 inches.
- Three vertical simplex lubricating oil pumps, 8 inches by 10 inches by 12 inches.
- One vertical duplex oil cooler circulating pump, 10 inches by 12 inches by 12 inches.
- Two Metropolitan double tube injectors size about No. 14½.
- One donkey boiler injector Metropolitan double tube type.

Ferryboat Poughkeepsie, Operated by the Westinghouse-Winton Diesel-Electric System, One of the First Commercial Vessels to Be Operated by Electricity

The Electric Ferryboat Poughkeepsie

Economical Operation Secured by Diesel-Electric-Geared Drive Installed in Hullfin Type of Vessel

By William H. Easton*

THE ferryboat *Poughkeepsie*, which is now in operation between Poughkeepsie and Highland on the Hudson River, is one of the most remarkable craft afloat. She is one of the first commercial vessels to be propelled by electricity; she is the first Diesel electric ferry to be put into operation; she is the only Diesel-electric-geared vessel in existence; she is the first to be constructed with a hullfin; and she has been especially designed to act as an ice-breaker. Because of this unusual combination of unique features, she has attracted a great deal of interest in the shipping world. She was completed in September, 1922, but at first was not able to make her required speed. This difficulty has been overcome, however, and she was recently placed in regular service.

Her propelling machinery is, of course, the most important part of her equipment. This consists of two 125-horsepower Winton Diesel engines, each of which drives a 90-kilowatt Westinghouse generator, which in turn furnish power to two 100-horsepower Westinghouse motors geared to the propellers.

FUEL CONSUMPTION LOW

There are several reasons why this form of drive was adopted. The most important is its high fuel economy. There is every reason to believe that the *Poughkeepsie* can develop a brake horsepower per hour on less than a half a pound of oil, whereas she would certainly require over a

pound of oil to develop the same amount of power, if she had the most efficient form of steam engine. In addition, she has no standby losses whatsoever. Consequently, when sufficient data are accumulated it is fully expected that the daily fuel cost of the *Poughkeepsie* will prove to be about one-third of that required by a steam operated vessel of similar power and hull size.

Another advantage is the compactness of the machinery. It can all be contained within the hull without a superstructure, leaving the main deck perfectly clear and providing room for four lines of automobiles in addition to the passenger cabins on either side. The *Poughkeepsie's* car capacity is therefore practically double what it would be with steam propulsion.

VESSEL CONTROLLED FROM PILOT HOUSE

Finally, the pilot has absolute control over the movements of the vessel. By merely moving a small handle located behind the wheel in each pilot house, he can start, stop, reverse, or change the speed of the boat without the loss of an instant's time or the slightest opportunity of having his signal's misunderstood. So quick is this control that the *Poughkeepsie* can be brought from full speed ahead to full speed astern in less than a minute.

To look at the *Poughkeepsie*, she appears to be broad, shoal, and of very light draft. This is not the case, however, for under her visible hull is a second one, known as the

*Westinghouse Electric & Manufacturing Company.

"hullfin," which is a long and narrow stream-line projection, like an enlarged keel. It contains the propeller motors, gears and shafting, and carries the propellers at its ends. Its chief purpose is to place the propellers under the boat, where they are always immersed in solid water. It also enables the *Poughkeepsie* to act as an ice breaker. Instead of wedging into the ice, as a boat with a standard hull will do, the broad end of the *Poughkeepsie* rides over it, crushes it and then pushes it aside. The position of the propellers on the hullfin prevents them from being injured during the process.

No very heavy ice has been encountered in the river so far this winter, but it is expected that the *Poughkeepsie* can be kept in operation with even the maximum thickness of ice, which sometimes exceeds two feet at this point.

DETAILS OF CONSTRUCTION

The *Poughkeepsie* was built in the Mill Basin, Brooklyn,

yards of the Atlantic, Gulf & Pacific Company for the Poughkeepsie & Highland Ferry Company. She has a length over guards of 140 feet, beam over guards of 52 feet, total draft of 10 feet, hullfin draft of 6 feet, and a displacement of 400 tons. Her hull is of steel and her superstructure of wood with steel supports, trusses and tie rods. At each end of the hull there is a special system of framing and extra heavy plating designed to provide the resistance necessary for the ice crushing service. The hull itself extends to the fender guards furnishing maximum stability and eliminating the overhanging guards and braces in general use.

PROPELLING MACHINERY

The engines are of the Winton model W59 Diesel type, with six $7\frac{1}{2}$ by 11-inch cylinders, and operates at 450 revolutions per minute. The main generators are rated at 90 kilowatts each and supply 250-volt direct current. Two 9-

One of the Poughkeepsie's Two Main Generating Units, Consisting of a 125-Horsepower Winton-Diesel Engine Driving a 90-Kilowatt Westinghouse Generator, with a 9-Kilowatt Westinghouse Exciter

kilowatt Westinghouse generators, driven from the main engines, furnish excitation for the main generators and motors, as well as power for lighting and other purposes when the vessel is in operation.

For use when the main engines are shut down, there is a $7\frac{1}{2}$ -kilowatt gasoline-driven generator. This supplies sufficient power for lights and also for operating a small motor-driven compressor which provides air at 600 pounds pressure for starting the main engines.

The main engines operate continuously at constant speed in one direction only during the operation of the boat, all speed changes in the boat's movements being made by chang-

connected directly to the propeller shaft. It was not possible, however, to obtain full speed with the 48 by 26-inch propellers then used. Messrs. Tams & King were retained as consulting engineers to correct this trouble, and at the suggestion of their Mr. A. B. Raymond, herring-bone gears, giving a $3\frac{1}{4}$ to 1 reduction, were installed between the motors and the propeller shaft, and 60 by 60-inch, semi-steel Kearsfott propellers, to operate at about 220 revolutions per minute were substituted for the original ones.

The result of these changes was the gain of about 45 per cent in the *Poughkeepsie's* speed, so that she now runs at about 9 miles per hour. Normally both motors and both pro-

Arrangement of the Poughkeepsie's Two 100-Horsepower Westinghouse Propeller Motors. The Propeller Shaft Carries a Propeller at Each End, and Both are Normally Operated by the Two Motors. The Motors are Connected to the Gears Through Flexible Couplings. A Universal Joint, Connecting the Two Halves of the Propelling Shafting, Eliminates the Necessity for Perfect Alinement

ing the speed or direction of rotation of the motors. Either or both engines can be used at any time.

A small rheostat, located under the floor of each pilot house and operated by the pilot's controller, controls the motors by varying the voltage and the direction of the main generator field-current supplied by the exciters. The amount of current handled by the rheostat is small, so that the control equipment is very light. In addition to the controllers in the pilot houses, there is a third one in the engine room for emergency purposes. A switch prevents the use of more than one controller at a time. Should the circuit-breakers, which protect the main circuits by opening automatically on overloads, operate and cut off the current to the propeller motors, they are reset by pressing a button located on each controller. All the controlling and switchboard apparatus is of Westinghouse make.

REDUCTION GEARS INSTALLED

As originally designed, the propeller motors, which operate from 600 to 720 revolutions per minute, maximum, were

connected directly to the propeller shaft. It was not possible, however, to obtain full speed with the 48 by 26-inch propellers then used. Messrs. Tams & King were retained as consulting engineers to correct this trouble, and at the suggestion of their Mr. A. B. Raymond, herring-bone gears, giving a $3\frac{1}{4}$ to 1 reduction, were installed between the motors and the propeller shaft, and 60 by 60-inch, semi-steel Kearsfott propellers, to operate at about 220 revolutions per minute were substituted for the original ones.

The result of these changes was the gain of about 45 per cent in the *Poughkeepsie's* speed, so that she now runs at about 9 miles per hour. Normally both motors and both propellers are operated so as to give ample power and eliminate the drag due to the forward propeller, but either motor or either propeller can be cut out, if desired.

In the opinion of Mr. Raymond, this geared arrangement forms an excellent drive and one that deserves careful consideration in designing future boats of this general character. The combined weight of the high speed motors and the gears is less than that of motors of sufficiently slow speed without gears or direct connection to the shaft; a low shaft line is made possible while the motors are raised up where they are accessible, well ventilated, and kept clear of the bilge; perfectly silent operation is obtained at the low peripheral speeds employed; and the life of the gears should be practically unlimited.

EQUIPMENT DETAILS

The two cabins of the *Poughkeepsie* will seat 190 passengers. If traffic demands, these cabins can be put on the upper deck. The heating apparatus consists of an Arcola steam heater. An air-operated Strombos horn is used for

signalling. Fuel-oil tanks with 4,400 gallons capacity—over a month's supply—are located in the compartments at the ends of the hull. The steering gear is of the Thames multiple hand-operated type.

Albert B. Hager, vice-president of the Atlantic, Gulf & Pacific Company, is responsible for the *Poughkeepsie's* construction. Special credit must be accorded S. A. Crum, president of the Poughkeepsie & Highland Ferry Company, for his enterprise in building a boat that marks such an important step in the advance of marine engineering.

Car Ferry Designed to Link Branches of Missouri-Illinois Railroad

IN order to connect the two sections of the Missouri-Illinois railroad, of which ninety miles of main line are in Illinois and forty in Missouri, divided by the Mississippi river, this company recently added the side wheel car ferry *Ste. Genevieve* to its equipment. This ferry was constructed by the Charles Ward Engineering Works, Charleston, W. Va., from designs of Cox and Stevens, naval architects, New York. The ferry is actually intended to act in the capacity of a bridge in handling the traffic of the railroad, which includes a considerable tonnage of coal. The run is extremely short but the ferry will be used continuously so that a craft of rather unusual type was determined upon.

PRINCIPAL DIMENSIONS

The hull is built of steel to the following dimensions: Length, 285 feet; depth, 11 feet; beam, molded, 54 feet; beam over guards, 86 feet. The ferry is of the single deck side wheel type carrying three tracks with a steel deckhouse containing the machinery, boilers and coal bunkers.

The sponsons carrying the outboard bearings to the wheels are supported by a structural frame spanning the track, and the pilot house, which is of wood, is supported by a structural frame forward of the deckhouse.

PROPELLING MACHINERY

The propelling machinery consists of two simple engines with cylinders 22 inches in diameter by 8 feet stroke for which steam is supplied at 200 pounds per square inch by 6 boilers 44 inches in diameter, 26 feet long, each having ten 6-inch flues. The boilers are equipped with steam jets for cleaning.

Bow View of Car Ferry *Ste. Genevieve* Showing Arrangement of Tracks and Deck Houses Containing the Propelling Machinery

The paddle wheels are 28 feet in diameter by 12 feet wide. Two rudders are fitted aft which operate by hand or steam power. Under the conditions in which the ferry operates it is necessary that when fully equipped, with the bunkers filled and carrying a load of ten cars of 82 tons each, the draft shall not exceed 5 feet. This was the determining factor in calculating the scantlings of the craft. Wherever possible the weight of the structure was kept to a minimum without sacrificing strength. The requirements that the hull shall be sufficiently rigid to permit carrying a locomotive of 160 tons weight added further complication to the problems of design.

In determining upon the engineering features of this ferry careful attention was given to the local conditions under which it would be required to operate—the shortness of the run and the difficulties to be met in navigating the river. It was determined that a simple non-condensing engine with the customary river type of boiler, in view of its simplicity and ruggedness, was the best possible combination of power equipment.

Car Ferry *Ste. Genevieve* Built by Charles Ward Engineering Works for Connecting the Main Line of the Missouri-Illinois Railroad Company Across the Mississippi River

New Railway Dry Dock Operating in Baltimore Repair Yard

AMONG the various forms of ship repair equipment recently taken over by the H. E. Crook Company, Baltimore, Md., from the Union Shipbuilding Company in the operation of the repair facilities of this yard is a new 4,000-ton railway dry dock designed by the Crandall Engineering Company of Boston. This dock was put in commission late in the fall of 1922 when the steamship *Anacortes*, having a displacement of 4,975 tons, was hauled out of the water for repairs. Incidentally, this ship, having a draft of 8 feet 6 inches forward and 15 feet 6 inches aft, was a 25 percent overload for the dock.

The field engineering force of the Crandall Company carried out the construction. The cradle and track are of heavy timber construction built of long-leaf yellow pine and Douglas fir. The general dimensions of the new dock are: Length on keel blocks, 360 feet; breadth, 70 feet; draft on keel blocks forward, 15 feet; draft on keel blocks aft, 20 feet. It is so built that the keel block line is nearly level so that a ship while being docked is in a horizontal position at all times. The entire dock is decked over forming a safe and convenient platform where the men may carry on their work efficiently. Uprights supporting the docking platforms are erected on each side of the cradle. Winches for operating the bilge blocks along the slides are mounted on the docking platforms. The bilge blocks are equipped with a patent releasing mechanism enabling the blocks to be quickly released and replaced under full load.

The track is of the four-way type resting on a foundation of yellow pine piling driven to hardpan and accurately cut to grading. The cradle runs on the track supported on free rollers working on heavy plates attached to the track and the cradle. The under water portion of the track was built

Hauling Out the Steamship *Anacortes*, with a Displacement of 4,975 Tons, on New Crandall Railway Dry Dock in Baltimore

ashore then launched and carefully sunk into place between guides and fastened in position after a further check to assure correct alinement.

The cradle is drawn by six 2¼-inch marine railway chains attached to the cradle by means of an equalizing device which makes the pull on the several chains uniform. A powerful hoisting machine, composed of a train of heavy spur gearing actuated by a 250-horsepower alternating current motor running on 440-volt, 3-phase, 25-cycle current is used to operate the cradle chains. Automatic brakes are provided and also hand brakes for emergency. Two speeds are arranged for hauling the ship out of the water—the slow speed being capable of lifting the full load in forty minutes.

Crandall 4,000-Ton Railway Dry Dock Installed at Yard of Union Shipbuilding Company, Baltimore

Four-Cylinder Stephen-Sulzer Engine, Designed to Develop 1,600 Brake Horsepower

Diesel Engine Developments in Great Britain

By Our Special London Correspondent

There appears a distinct likelihood of competition between two and four cycle Diesel engines becoming much more acute in the near future than it has been in the past. Hitherto the vast majority of motorships have been equipped with machinery operating on the four cycle principle, and it will probably not be an over-estimate to say that 90 percent of the large oil engined ships afloat are equipped with motors of this class. The belief which engineers hold in the future of the two cycle engine is, however, indicated by the fact that among the 20 or 30 firms in the United Kingdom which have taken up the manufacture of large marine oil engines, some 75 percent have decided to adopt the two cycle type.

IN view of the order that was recently placed by the Union Steamship Company of New Zealand, for a 20,000 ton motor liner in which Sulzer two cycle machinery of 13,000 shaft horsepower will be installed, considerable interest attaches to the completion of the first twin screw sets of this type that have been built in Great Britain. Several ships equipped with Sulzer engines are now in service but the machinery in all cases has been built either almost completely or mainly in Switzerland, and not by their British licensees.

On the Clyde, Messrs. Alexander Stephen & Sons, Limited, are now installing two Stephen Sulzer engines each of 1,600 brake horsepower in the motorship *Dalgoma*, an 11,000 ton cargo vessel for the British Indian Steam Navigation Company, which will run her trials at the end of April. At Denny's yard on the same river, the 10,000 ton tanker *Scottish Borderer* is fitting out and in this vessel two Denny Sulzer engines of 1,250 brake horsepower each will form the propelling equipment. In both cases the whole of the machinery has been built by the Scottish firms, only one or two parts such as fuel valves being supplied by Sulzers themselves from their Swiss works.

Curiously enough there are considerable points of difference in the motors built by Stephen's and Denny's respectively, as will at once be seen by an inspection of the illustrations. In the former, what may be taken as the more modern system is adopted. There is no scavenging pump driven direct off the engine and the necessary scavenging air is supplied from separate electrically driven turbo blowers.

SCAVENGING BY TURBO BLOWERS

It may be assumed that the power needed for the operation of these blowers is about 5 to 7 percent of the total output of the main engines. Thus with the two sets operating at full power developing 3,200 brake horsepower an electric motor of 200 brake horsepower driving the blower is found to be suitable. Actually two turbo blowers are fitted, one being a standby and the other supplying the necessary air to both propelling engines. It may be remarked that the construction of the electric motors for this purpose calls for some special care, on account of the fact that they run at 2,750 revolutions per minute and have to be of the direct current type operating on the fixed circuit of 220 volts.

CYLINDER SIZES

These engines have cylinders of 26.77 inches bore and 43.31 inches stroke and run at the relatively low speed of 85 revolutions per minute. Diesel motors with cylinders of the same size, but having a speed of 100 revolutions per minute are now being built, when the output is 2,000 brake horsepower. It is interesting to note that in four Sulzer type engines which are to be installed in the motor liner referred to above, the four cylinders of each engine are of 27.17 inches bore and 38.58 inches stroke, but the speed of revolution is greatly increased, about 135 revolutions per minute being the normal. The output in this case is 3,250 brake horsepower for each engine.

In the Stephen Sulzer motor there is a single two stage air compressor at the forward end and a group of three pumps driven from the crankshaft, two horizontal and one vertical. One of these supplies oil to the crankcase at about 300 pounds per square inch, which is of course much higher than the main lubricating oil supply pressure. Another is a bilge pump and a third a fuel transfer pump. Sea water is utilized for cooling the jackets and covers, while fresh water is employed for the pistons, separate electrically driven centrifugal pumps being installed in the engine room for this purpose.

CONTROL LOCATED AT TOP OF CYLINDERS

Unlike most other types of marine Diesel engine, the control station is located on a level with the top of the cylinders.

One of the Turbo Scavenging Blowers Used in Connection with the Stephen-Sulzer Engine

Maneuvering and reversing are carried out in a simple manner since there is only one fuel and one starting air valve in each cylinder actuated by ahead and astern side-by-side cams on the camshaft. The usual Sulzer scavenging system is employed, in which, besides the row of ports in the bottom of the cylinder for the admission of scavenging air, is a further series of supplementary ports above, through

The First Denny-Sulzer Engine. Brake Horsepower at 120 Revolutions per Minute, 1,250

which air is only admitted after the piston has covered the exhaust ports as it has moved upwards.

In the Denny Sulzer engine, turbo blowers are not utilized for scavenging purposes. It will be noted that at the forward end of the engine is arranged a large piston scavenging pump driven off the crankshaft in addition to the three-stage air compressor. There is probably not much difference in weight and cost between the two systems although, if anything, the advantage rests with turbo scavenging. It is, however, generally thought that for most engines, even of big size, turbo blowers will be used in the future. The power of 1,250 brake horsepower is developed at 120 revolutions per minute, the cylinder diameters being $23\frac{1}{2}$ inches and the stroke 41.7 inches.

In the ship in which the two Denny Sulzer engines will be fitted, steam auxiliaries are to be used throughout and it is naturally desired to have as few as possible in operation when the ship is at sea since oil fired boilers are notoriously uneconomical. The engine is therefore made self-contained and the group of three pumps at the forward end referred to in connection with the Stephen Sulzer engine are utilized for other purposes. One pump is for supplying cooling water to the cylinder jackets and covers, another serves as a bilge pump and the third as a main lubricating oil pump.

At the back of the engine, driven by levers from one of the crossheads is another group of pumps for piston cooling water, crosshead lubrication and the transfer of fuel respectively. Thus when the vessel is at sea no independently driven auxiliaries are needed apart from the small steam driven dynamo supplying current for electric light throughout the ship. Another point in favor of steam driven auxiliaries is that they are less costly although far less

economical in fuel. There are, however, special reasons for using steam for this purpose in tankers on account of the suitability of steam engines for driving the cargo pumps, but generally speaking the employment of electricity for operating all the auxiliaries on modern motorships is now becoming almost universal.

FASTEST TRANSATLANTIC MOTOR LINERS NOW POSSIBLE

It is a matter of interest that, based upon their experience with a single cylinder 2,000 brake horsepower two cycle engine which Sulzers built some years ago, they have now designed eight cylinder motors of 10,000 brake horsepower which it is understood will be built under the usual guarantee. Thus with a quadruple screw arrangement the fastest transatlantic liners could be equipped with Diesel machinery.

The engine in question would develop its power at 170 revolutions per minute and have cylinders of 33.47 inches diameter and 43.31 inches stroke. The mechanical efficiency would be 74 percent and the indicated horsepower 12,600. The weight of the engine without accessories would be 525 tons and scavenging air would of course be supplied from electrically driven turbo blowers. The piston speed would be 1,230 feet per minute, which is admittedly somewhat high and the mean indicated pressure about 95 pounds per square inch. For each engine the power absorbed by the blower would be 700 brake horsepower.

In a quadruple screw arrangement of 40,000 shaft horsepower there would be four auxiliary engines each of 1,000 brake horsepower driving dynamos. These would run at 240 revolutions per minute. The proposal is interesting as showing the confidence which Diesel engine builders now feel in developing motors of large power.

High Pressure Gas Regulator

FOR the control and delivery of acetylene, oxygen, hydrogen and other high pressure gases, the Alexander Milburn Company, Baltimore, Md., has developed the gas regulator shown. Features of this device are said to be simplicity, ease of assembly, direct action and accurate regulation.

The regulator comprises a front cap containing an adjusting key, top spring button and tension spring. The body contains a flexible metal diaphragm in front, soldered in place. Over the diaphragm is screwed a bronze diaphragm plate or spring button to hold the tension spring. Inside the body is a fixed nozzle, containing a loose operating pin. Over the nozzle is loosely assembled the valve sleeve which has a row of gas ports drilled around its circumference and carries the valve seat. The seat closes against the nozzle by initial gas pressure on the valve sleeve and the pressure of a compensating spring resting in the recessed back cap.

The loose operating pin inside the nozzle is actuated at one end by a depression of the diaphragm and at the other end by pressure of the valve seat.

The seat of the regulator closes *with* instead of *against* the pressure, enabling the seating to be effected by a sealing pressure of several pounds instead of hundreds of pounds with attendant risk of damaging or splitting the seat, as in the case of regulators where the seat is yoked to the diaphragm. The closing of Milburn seat is independent of the diaphragm.

The valve is closed by the rear pressure of the compensating spring, assisted by initial gas pressure. When the adjusting key is turned to the right, the tension spring depresses the diaphragm, moving the loose pin, which forces the sleeve back, unseating the valve and permitting gas to enter through ports in the sleeve. The gas then passes through the nozzle to the diaphragm chamber and thence

to the low pressure gage and through the outlet port. When multiplied gas pressure exceeds the tension of the adjusting key spring, the diaphragm is released, permitting the loose pin to advance and letting the valve sleeve close the valve by pressure of the rear compensating spring.

Milburn High Pressure Gas Regulator

Selection of the Best Kind of Propelling Machinery*

Comparison of Vessels Equipped With Various Types of Propelling Machinery — Discussion of Factors Influencing Selection of Best Type

By J. L. Ackerson†

NEVER before has the marine engineering fraternity had so many different types of propelling machinery to select from, and there is no empirical formula which can be applied to help select the best type. The problem of the shipowner in this respect is the most important one he has today. Among the many factors to be considered in deciding what is the most suitable type are reliability (this is the most important single factor, for without reliability other advantages are very much discounted); economy in operation, initial cost, and weight, the relative importance of the last three depending on the type of ship under consideration.

RELIABILITY

Reliability is something less tangible than the other three and responsibility less easily placed, because the factors controlling reliability emanate from two different sources: (1) The owner, through the selecting of competent personnel; and (2) the builder. No matter how well a machine has been designed and constructed, if placed in the hands of an incompetent operator, it will become unreliable; and *vice versa*, no matter how good the operating engineer, if the proper factors have not been used in the design and care in the construction, then the machinery is again unreliable; so that it is absolutely necessary for the operator thoroughly to understand and be whole-heartedly in support of any new design, and for the designer to realize that the cost of fuel per horsepower, while important, is not the only consideration. In the past five years we have had a very costly experience through sending to sea a large number of units (the design of which to begin with is questionable) in charge of engineers who were only half trained.

ECONOMY

Economy in operation (that is, the fuel per horsepower) and initial cost usually bear a very close relation to each other, and it is only a question of figures to determine whether any particular type is worth the money as compared with any other type; and here again the type of vessel and the trade the vessel is employed in play an all-important part, as for example, most tramp steamers over a cycle of, say seven years, are laid up for considerable periods at a time owing to there being no freight. During this lay-up the portion of expense due to fixed charges is going on all the time, while that portion consisting of fuel and supplies and operating personnel stops when the ship is laid up.

WEIGHT

Weight is the least important except in the case of special types like shallow-draft boats, express-type steamers, warships, etc., because except in special trades—*viz.*, coal, ore or oil-carrying—it is seldom that a ship is loaded down to a loaded draft mark, even when full of cargo.

With this brief introduction I will now present comparisons of the following different types of machinery and ships:

Geared turbines with Scotch boilers.

Geared turbines with watertube boilers.

Reciprocating steam engines with Scotch boilers.

Reciprocating steam engines with watertube boilers.

Diesel engine 4-cycle.

Diesel engine 2-cycle.

For 5,000-ton freighter at 10½ knots.

For 7,500-ton freighter at 11 knots.

For 8,800-ton freighter at 10½ knots.

For 10,000-ton freighter at 12½ knots.

For 10,500-ton tanker at 10½ knots.

For 17,000-ton displacement passenger ship at 15 knots.

From Table I the one outstanding feature is the greater savings for Diesel-engine ships in the long-voyage trades, and this is chiefly due to the saving of cargo space required for carrying fuel oil rather than to the saving in cost of fuel oil, operating personnel, and fixed charges. Also, that for short voyages the Diesel engine should be given very careful consideration before a selection of the type to be used is made.

The different comparisons show that there is not much difference between the weight of Diesel engines and steam reciprocating engines, but it should be borne in mind that for steamers up to 12 knots speed the revolutions per minute of the Diesel engine are considerably higher than those of the corresponding steam engines—in the ratio of about 110 to 75. This undoubtedly means a less efficient propeller for all single-screw types. On faster boats the advantages of the slower revolutions per minute gradually disappear. In comparing weights, allowance should be made for reserve feed water for the steamer; if this is done, steam-engine weights will invariably be greater than Diesel-engine weights for voyages of ten days and over, except in the case of larger power geared-turbine jobs than those now under consideration.

It should also be noted that, whereas powers of four to five thousand are possible on single-screw steam installations, it is necessary to go to twin-screw installations for Diesel engines. This incurs an extra cost in hull construction, necessitating two shaft alleys which cut up the after holds and make it more difficult to stow cargo, as well as actually decreasing the cubic of the holds.

Originally it was my intention to resolve the saving in cargo space due to fuel-oil requirements into dollars per year, but owing to the uncertainty of freight rates I gave up the idea as being impracticable and have shown this advantage in tons per voyage. The alternative to carrying this large quantity of fuel oil would be to buy it at the ports of call. Which choice would be the better would depend, of course, on the price of the fuel oil at, and the freight rate to, those particular ports.

The initial costs listed in Table I may be open to criticism, owing to prices being so spotty and varied at the present time. These prices are based on firm quotations of the lowest reputable bidder and include machinery installed ready for use. The same remark applies to weight. Different builders vary considerably, but, whatever error there is, the percentage of error will be the same for all types and will be in the same direction; and as it is the difference in cost and the difference in weight which we are most interested in, the percentage of error will be very small.

The machinery weights do not include hull engineering or any portion of the machinery usually located in the engine room but necessary for deck machinery only, such as auxiliary generating sets for generating electricity to be used on electric deck machinery.

* Paper read before the Society of Naval Architects and Marine Engineers, New York, November 9, 1922.

† Vice-president, Merchant Shipbuilding Corporation, Chester, Pa., and president, Atlantic Coast Shipbuilders' Association.

TABLE I

Type of Ship	Machinery		Cost of Fuel at Sea per Day	Cost of Fuel per Year		Cost of Operating Personnel	Depreciation Charges 15%	Total Cost per Day	Water Up Tank Capacity, Tons	Fuel Oil Required for Following Distances Allowing 15% Margin, Tons	Cargo Space Taken Up for Fuel Oil for Following Distances, Tons

R. E.—Reciprocating Engine
G. T.—Geared Turbines

S. B.—Scotch Boilers
W. T. B.—Water Tube Boilers

R.E.—Reciprocating Engine
G.T.—Geared TurbinesS.B.—Scotch Boilers
W.T.B.—Water Tube Boilers

I have not given the cubic required for the machinery space, because in all cases the space required is so near the 13 percent required by the United States tonnage rules as not to justify the loss of the 33 percent deduction to gross tonnage, which is permitted when machinery space is at least 13 percent of the cubic of the ship.

I have not dealt with the engines which offer the greatest saving in space and weight, because up to the present time none has been built in this country, but it would appear to me that the opposed piston type of engines like the Fullagar and the Doxford offer many advantages that cannot be overlooked by the prospective shipowner.

From reports available, the *Yngaren*, fitted with a 3,000-horsepower opposed piston-type engine, made by the Doxford Company, has given an excellent account of herself for her maiden voyage from the British Isles to Australia and back. This engine offers one or two very desirable features, *viz.*, a slow-running engine for comparatively large powers, with the consequent efficient propeller, considerably smaller engine-room space and one shaft alley only.

Owing to the Diesel engine builders standardizing around an engine of 2,500 shaft horsepower, I have used this power upon ships of 7,500 to 8,800 tons and on a 10,500-ton tanker. This assumption makes machinery for these types cost and weigh about the same but gives us slightly different speeds. (The above figures hold good only so far as new machinery is concerned.)

It so happens, however, that at the present time there is hanging over the market a very large tonnage owned by the Emergency Fleet Corporation and available at very much lower prices than the present actual cost for replacing the same.

To convert any one of these 7,500 to 12,000-ton steamers into Diesel engine-driven boats, with 2,500 shaft horsepower Diesel engines, maintaining the existing auxiliary steam-driven machinery and deck machinery, would cost approximately \$400,000, and this same change, together with changing the auxiliaries and deck machinery to the electric drive, would cost in the neighborhood of \$550,000.

The first proposal would save the shipowner approximately 18 tons of oil a day; the second would save him about 22 tons of oil a day. For 200 days a year at sea and 165 days in port at \$10 a ton for oil, the total saving for steam auxiliaries and Diesel propelling engines in oil would be about \$36,000, and the extra for fixed charges would be \$60,000. For Diesel propelling engines and electric deck machinery the initial cost would be in the neighborhood of \$550,000. Saving in fuel oil would be 22 tons for 200 days and 5 tons for 165 days at \$10 a ton—\$53,000—and the extra due to fixed charges would be \$83,000. The extra cost of lubricating oil for the Diesel engine will be offset by the decrease in cost of operating personnel, so that, assuming the same price, whether the owner will run the ship as a motorship or as a steamship, the conversion is not justifiable except for the long voyages; but if these ships can be bought for conversion purposes at \$30 a ton less than would be paid to continue as steamships, the fixed charges are reduced on a 10,000-ton ship to \$37,000, and for almost any trade this change would be justifiable.

For conversion from steamers to motorships under the Shipping Board plan, where new Diesel machinery must be had, it would appear that the larger boats offer the best possibilities.

Before closing I should like to say that, while I have taken 200 days at sea and 165 days in port per year for all the types except the tanker, this figure must, of course, depend on the trade the vessel is employed in. There are some trades where a ship is in port almost half the time, and it must be remembered that while a ship is in port it is not earning anything while the fixed charges are still going on. Therefore the more costly propelling machinery is at a disadvantage as

compared to a cheaper type running only a small portion of the time.

While I consider Table I a good guide, the only way the best type can be selected is by a careful comparison of the different types in the particular trade an owner wishes to engage in along the lines given in the table, taking into account the character of the freight, length of voyage, freight rates, cost of fuel oil at ports of call, etc.

Diesel Engine Electric Ship Propulsion*

By W. H. Wild†

SINCE 1904 there have been completed and placed in service approximately eight hundred motorships above two hundred brake horsepower capacity each and, no doubt, the fuel economy of the Diesel engine, as compared with steam driven machinery, has been the greatest factor in this rapid development.

Diesel electric drive permits of single screw operation, even though more than one engine is used, and the most efficient propeller speeds may be adopted regardless of the number or speed of the engines used. This means it will be possible to standardize the engine, and the designing engineer is at liberty to produce the most efficient and reliable engine without limitation as to speed or size. The engine that lends itself best for manufacture may be adopted and then install two, three, four or more engines depending on the power required. This will reduce the cost of manufacture.

SAVINGS IN WEIGHT AND SPACE

In some ships space and weight are of prime importance. The electric drive does not require the generating sets to be placed in any definite position with respect to the propeller shaft and, therefore, the equipment can be installed to the very best advantage. The question of weight is largely dependent on the rotative speed of the engine and since the electric drive permits using a multiplicity of engines it will be found that the weight of the complete equipment including the electric apparatus will frequently be in favor of the electric drive.

The loss of energy in the electrical apparatus is often pointed out as a serious handicap. This loss, in direct current equipments, may amount to as much as 17 percent, and with alternating current equipments somewhat less, when compared with direct connected propellers running at a speed which is suitable for the highest propeller efficiency. This loss is offset in electric driven ships by using single screws in place of twin screws; adopting the most efficient propeller speed; the most efficient engine speed, and in many other ways. When less than full speed is required one or more units may be shut down thereby effecting a large saving in operating costs.

PILOT HOUSE CONTROL POSSIBLE

The maneuvering advantages of electric drive are of considerable importance for many types of ships such as barges, tugs, fishing boats, ferries, coastwise ships, etc. It also provides a simple means of cutting engines out of service for overhaul at sea or for making simple adjustments. Pilot house control can readily be installed, if desired.

Nearly all motorships are being fitted with electric auxiliaries and Diesel driven auxiliary generators. The auxiliary generating units may often be dispensed with in the electric driven ship with the possible exception of a small set for port use; the main engine generators being used for supplying auxiliary power. In many ships this would permit a saving of thousands of dollars in first cost as well as

*From a paper read before the Ocean Engineers' Association, New York.
†Marine Department, General Electric Company, Schenectady, N. Y.

a large saving in upkeep. This advantage is of greater or less importance, of course, depending on the relation of auxiliary power required as compared to the main propelling power.

RELIABILITY AND CONTINUITY OF SERVICE

Finally, those interested in marine activities desire most reliability or continuity of service. The equipment which can demonstrate the greatest reliability, with the other characteristics reasonably comparable, is bound to find an important place in ships' drive. As for the electrical equipment the major part of all movement is simple rotation, which enhances the great reliability of this apparatus. It has been in successful operation for years on land in every conceivable power application and in the past 10 years thousands of horsepower have been applied to the successful propulsion of ships.

When the electric drive is applied to motorships it is the practice to install two or more engine-generators and mount two motors on the propeller shaft of single screw ships which in reliability is equivalent to a twin screw ship except for the fact that but one propeller is used. Therefore, while the power is generated by engines which involve reciprocating motion, the power is transmitted to the propeller shaft through a motor which involves simple rotation only, and the generating plant can be composed of a sufficient number of units to insure 100 percent continuity of service without sacrificing its economy.

Electric Submerged Log

AN electro mechanical log which will register accurately at low speeds of a vessel is being manufactured by the Electric Submerged Log Company, 33 and 35 Eastcheap, London, E. C. 3, England. The log consists of an electro mechanical device fitted to the hull of a ship at a predetermined depth and at a point where wave and propeller disturbances do not occur. The principle upon which the device works is the conversion of the mechanical action

of a small rotator into electric impulses which are transmitted by wire to a registering device in the wheel house.

The submerged unit of the equipment is connected to the hull of the vessel so that a short section containing the rotator projects outside the hull while another part is inside the vessel. The interior mechanism includes a flange, sluice valve, main tube, stuffing box and a handle. The exterior mechanism comprises a submerged support, an electrical contact casing and the rotor. The contact casing contains the terminal contact of an insulated wire connected to the batteries and the indicating apparatus. An insulated spring makes contact with the commutator or make-and-break disk. The rotator is secured to its ring by a key and screw, the motion being transmitted from the shaft through double worm and wheel gears to the make-and-break disk. This disk makes twenty revolutions per mile of ship's travel.

The distance registering apparatus in the wheel house is calibrated to indicate distances of one-twentieth of a mile corresponding to the rotation of the make-and-break disk up to 10,000 miles. A panel comprising a voltmeter and table of speeds is also provided, with three switches used to connect the voltmeter to a test battery, to connect the recording dial in circuit and to connect a buzzer used for determining the speed of the vessel. This buzzer gives an audible signal every twentieth of a mile traversed and, with the aid of a stop watch, the actual speed can readily be determined.

Notes on Sublimed Blue Lead

SUBLIMED blue lead in the dry state as it comes from the smelter is used in the manufacture of paints and rubber. The Eagle-Picher Lead Company sells the dry product to paint manufacturers and to rubber manufacturers. It also grinds the sublimed blue lead with pure raw linseed oil and markets it in paste form ready to mix with oil, drier and thinner for rust-proofing purposes.

LINSEED OIL

The vehicle is just as important as the pigment in determining the quality of a rust-proofing paint. There has been a long sustained effort on the part of paint technicians to develop other oils that could be substituted for a linseed oil, but up to the present time there is no oil that can be counted on to give the service that can be obtained with pure raw linseed oil.

Boiled linseed oil is specified by many for use with Sublimed Blue Lead because it dries quicker. Raw linseed oil can be given the same drying characteristics by adding suitable drier, and many believe that superior durability is obtained with raw oil.

Linseed oil has been exhaustively studied and engineering specifications for judging its suitability for paint surfaces have been prepared by, and may be obtained from, the American Society for Testing Materials.

PHYSICAL PROPERTIES OF SUBLIMED BLUE LEAD

Dry sublimed blue lead is a slate gray colored pigment of an almost impalpable fineness. With the exception of lamp black, sublimed blue lead is the finest pigment in use today, the particles being of the order of 0.0002 millimeter (0.2) in diameter. An idea of how small this really is may be obtained by comparing this with cement particles. Ordinary dry cement leaves approximately 22 percent on a 200-mesh screen, while sublimed blue lead will pass completely through a 325-mesh screen. A 200-mesh screen has 40,000 holes per square inch, while a 325-mesh screen has 106,000 holes.

The specific gravity of sublimed blue lead is 6.67, that is, it weighs 6.67 times as much as an equal volume of water. One solid gallon weighs 55.56 pounds and one pound bulks 0.018 of a gallon.

Propellers

How the Design of Propellers May Be Improved by Scientific Application of Model Test Data

By Alfred J. C. Robertson*

AT the November meetings of the Society of Naval Architects and Marine Engineers three scientific papers were read on Propellers and this is a fair indication that marine engineers and naval architects are coming to realize that the old methods of design are not sufficient to meet present conditions satisfactorily.

There is no doubt that the last few years have shown a notable improvement in the design of slow speed ships, which represent about 90 percent of vessels built, so that today designers are able to produce such ships with resistances of not more than say 10 percent above the minimum. Such results are largely due to increasing knowledge and understanding of model experiments, many of which, on low speed ships, have been made public in recent years.

On the other hand, it is not at all an unusual experience, when a change of propeller has been indicated, to find the speed of ship altered as much as a knot, representing perhaps 25 percent saving (or increase) in power.

CONDITIONS ALTERED BY USE OF GEARED TURBINES OR DIESEL ENGINES

The growing use of geared turbines or Diesel engines has at the same time largely discounted the value of accumulated propeller experience with reciprocating engines. These in most cases have been of the slow speed type permitting pitch ratios of 1.2, 1.3 and 1.4 whereas Diesel engines at present run at least 50 percent higher in revolutions for the same piston speed and machinery weight, giving pitch ratios of 0.80 to 0.95, with even higher relative speeds for single reduction geared turbines. For double reduction gearing lower speeds are available but the cost and weight of such gearing become almost prohibitive. In this case also, therefore, engineers are anxious to use propellers of the lower pitch ratios.

An additional incentive to the study of propeller design is provided in the case of Diesel engines because of the lack of elasticity of this type of prime mover. In reciprocating steam engines, if a propeller proves heavier in pitch or diameter than it should be, the revolutions of course drop, but it is usually possible to secure just as much power as was provided in the design by increasing the mean effective pressure in the cylinders.

In Diesel engines this advantage is denied us, because the design already makes use of the highest mean effective pressure which it is quite safe to use and any increase of that pressure is likely to produce troubles of various kinds through overheating, such as burning out valves and valve seats, cracking cylinder heads, etc.

EXPERIMENTAL TANK DATA NOT APPRECIATED BY PRACTICAL MEN

When therefore further knowledge of propellers is called for we naturally look to the work of the experimental tanks which have been of such assistance to us in the design of ships' hulls.

A considerable volume of such data has been available for some time but until recently it has been looked upon with grave suspicion by practical men; and this for three reasons: first, because practical men hardly understand or appreciate

the attitude of scientific men—that attitude which realizes and sometimes expresses a consciousness of vast realms of knowledge of which we have only touched the border, and secondly because propellers on ships will not give identical results with their models on model ships, and thirdly because of necessity model propeller data must be compiled independently of the ship with which it is desired to fit a propeller and the interaction between hull and propeller is still somewhat obscure.

But we are all becoming more scientific so that the first of these reasons should not deter us from the use of what knowledge exists and such knowledge will carry us along, perhaps not perfectly, but quite tolerably well, even if it be ultimately modified or displaced as they tell us Newton's most useful theory of gravitation has been displaced by more accurate knowledge.

MODEL TESTS DISPELLING DOUBT

The second reason is quickly vanishing as tests on full powered ships have been compared with the model tests and correction factors adduced, and the third reason will lose much of its force when we have before us such excellent papers as Professor Bragg's and Admiral Taylor's which deal very largely with the effect of a ship's hull upon the flow of water to the propeller.

Admiral Taylor's paper deals with tests made on one ship model with propellers of three different proportions and characteristics, located on a high and a low centerline, at three positions abaft the sternpost. In each case the model was driven by its own propeller at various speeds which practically covered the range of speeds at which a ship of the form of the model could be profitably operated. Careful records were taken and compared with the records made by the same propellers without the ship, i.e., in still water, and from these records the effect of the ship's wake upon the propeller, the suction or thrust deduction of the propeller upon the ship, and the hull efficiency resulting from these opposite forces, were arrived at.

Professor Bragg's paper records the results of many experiments to measure the speed of the water behind a ship where a propeller might be located.

ADVANCE OF PROPELLER MUST BE KNOWN

The significance of both of these investigations lies in the fact that the actual speed of a propeller through the water must be known, if the power it absorbs in torque or the power it delivers in thrust are to be known. Taylor's paper of course takes us further by giving us data as to whether the power delivered by the propeller (thrust) should or should not be equal to the resistance of the model as tested in the tank without the propeller (and usually designated E. H. P.).

As indicated, the speed of advance of propeller must be known. This is so because the slip of the propeller vitally affects its power to do work.

SLIP PERCENTAGE

Slip percentage is the ratio of the difference between the speed of advance of the propeller and its speed of advance as a screw through a solid. Without slip a propeller would

*Naval architect, Munson Steamship Line, New York.

advance the amount of its true pitch per revolution; if there is slip, the advance would be less.

The slip formula is therefore usually written

$$\frac{(N \times P) - (V_a \times 101.33)}{N \times P}$$

where N is the number of revolutions per minute, P is the pitch of propeller in feet and V_a is the speed of advance of the propeller in knots (i.e., speed of ship minus speed of wake water).

Nearly all propeller data is plotted upon this slip percentage, but this introduces us to one of the most difficult features in propeller analysis. Every propeller blade is possessed of a certain thickness and, if the face of the blade conforms to a true screw of uniform pitch, it will be found that the true pitch of the propeller, that is, the pitch at which the screw delivers no thrust, is somewhat greater than the face pitch, and the true slip for comparative purposes must be expressed as a function of this true pitch.

TAYLOR'S AND FROUDE'S PROPELLER DATA

In addition to the very extensive experiments on propellers carried out and made public by Admiral Taylor, Mr. R. E. Froude of England has also given us a somewhat similar series and all of Froude's propeller data is based on this true pitch of propeller. This has made it possible to express the results of the Froude propeller tests in a mathematical formula whereas Taylor's tests are simply presented as curves of performance plotted on face slip.

Each method has its own value. Taylor's method is probably more accurate for propellers similar to those tested, whereas Froude's propellers, being correlated by formula, are probably better for interpolation or extrapolation. Mr. T. B. Abell very carefully analyzed both sets of data and showed that substantially the results were the same though the general conditions of test as to size, design, location of propeller, etc., were different, and the method of tabulation differed fundamentally as stated.

In 1915 Schaffran in Germany proposed a method of setting forth the performance of individual model propellers in a manner readily applicable to full size screws.

SCHAFFRAN'S METHOD

This method is apparently becoming a popular one and Taylor has used it in his most recent contribution for furnishing us with the still water performance data of the three screws used.

Schaffran's data uses face slip ratio as abscissæ and curves of coefficients of torque and thrust and the resulting efficiency curve are plotted thereon. Writing

Q = Torque in foot pounds.

T = Thrust in pounds.

N = Revolutions per second.

V = Speed of advance in feet per second.

P = Face pitch in feet.

D = Propeller diameter, in feet.

We have

$$C_Q = \frac{Q}{N^2 P^3 D^2}$$

$$C_T = \frac{T}{N^2 P^2 D^2}$$

$$e = \frac{T \times V}{2 \pi Q N}$$

For ready application we may add

$$\text{Torque Horsepower Q. H. P.} = \frac{C_Q N^3 P^3 D^2}{87.535}$$

$$\text{and Thrust Horsepower, T. H. P.} = \frac{C_T N^2 P^2 D^2 V}{550}$$

Or more conveniently for ship problems we may use Froude's symbols:

$$R = \frac{\text{Revolutions per minute}}{100}$$

V_a = Speed of advance in knots

$$\text{Then Torque Horsepower, Q. H. P.} = \frac{R^3 P^3 D^2 C_Q}{18.908}$$

$$\text{Thrust Horsepower, T. H. P.} = \frac{R^2 P^2 D^2 V_a C_T}{117.24}$$

$$e = \frac{C_T}{C_Q} \times \frac{0.16127 V_a}{R. P.}$$

With a Schaffran diagram for a particular propeller it is very simple from trial trip results to calculate the wake

Taylor's Propeller No. 571

fraction and hull efficiency value and from these also the thrust deduction, and these elements will then be known for any new propeller for the same or a similar ship.

Taylor's paper shows that so long as the propeller is sufficiently far behind the stern post to avoid the erratic flow of the water there is no material difference in the above factors for considerable variation of diameter and pitch ratio of the screw, so that once the wake and thrust deduction are ascertained for a particular ship these may quite safely be assumed to be constant at the same ship's speed, and that at other speeds the variations are insignificant.

For vessels of other forms than that tested the paper by Professor Bragg may be referred to, and also papers by McEntee presented to the Society of Naval Architects and Marine Engineers in 1918 and 1919. From these it is pos-

sible to plot curves of wake and thrust deduction on the vertical or longitudinal prismatic coefficients.

HOLT'S THRUST MEASUREMENTS

Mr. C. F. Holt in 1920 contributed a valuable paper to the Institution of Naval Architects (London) which gave results of actual thrust measurements made on trials of several ships, and from these he deduced that the thrust developed at sea was about 7½ percent less than the model test results for a similar propeller whereas the torque was about 7½ percent higher, giving efficiencies of about 85 percent of the model efficiencies. These figures are probably somewhat pessimistic but in the absence of other data they should be accepted and applied in the analysis of trial trip results. This would mean that CQ should be increased 7½ percent and Cr reduced by the same amount when using propeller data with the Schaffran constants.

An example of the analysis of trial trip results is given in an appendix to this article. To utilize propeller data in the Schaffran form for design purposes it is necessary to adopt the method of trial and error. Assuming the pitch ratio, revolutions and horsepower are fixed it is required to ascertain the diameter and pitch. CQ or Cr are of course dependent upon slip and this also is unknown until pitch is known or assumed.

$$(1 - S) = \frac{V_a \times 1.013}{R \times P}, \text{ therefore } P = \frac{V_a \times 1.013}{R \times (1 - S)}$$

Then assuming say three values of slip the corresponding values of pitch are calculated and, pitch ratios being fixed, the diameters are ascertained and the horsepower may then be computed for the assumed propellers.

Curves of pitches and diameters will then be laid off on horsepower, and the required dimensions read off for the requisite power.

APPENDIX

Trial Trip Analysis

Example: Using Holt's factors for T.H.P. = 0.925 model T.H.P.
Model Q.H.P.
Q.H.P. = 0.925

Taylor's Propeller No. 571. (See Fig. 6, page 787, MARINE ENGINEERING AND SHIPPING AGE, December, 1922.) Diameter, 11 feet 9 inches; pitch, 8.45 feet; R.P.M., 125; S.H.P., 875; ship speed, 10.0; E.H.P., 438.

$$Q.H.P. = 875 \times 0.97 = 849 \text{ say } \frac{R^3 P^3 D^2 C_Q}{18.908 \times .925}$$

$$C_Q = \frac{Q.H.P. \times 18.908 \times .925}{1.952 \times 138 \times 603} = \frac{14,849}{162,434} = 0.0914$$

Face slip from diagram = 0.41

$$1 - S = 0.59, V_a = \frac{.59 \times 1.25 \times 8.45}{1.0133} = 6.15 \text{ knots}$$

$$\text{Wake} = \frac{10 - 6.15}{10} = 0.385$$

$$\text{Thrust H.P.} = \frac{C_r R^2 P^2 D^5 V_a \times 0.925}{117.24} = \frac{0.53 \times 0.925}{117.24} \times R^2 P^2 D^5$$

< 6.15 = 396

$$\text{Hull efficiency} = \frac{E.H.P.}{T.H.P.} = \frac{438}{396} = 1.106$$

$$\text{Thrust deduction } \therefore (1 - t) = (1 - w) \times 1.106 = 0.68, t = 0.32$$

$$\text{Propeller efficiency} = \frac{438}{849} = 0.466 \text{ (from diagram } 0.548 \times 0.85 = 0.466)$$

$$\text{Propulsive coefficient} = \frac{438}{875} = 0.500 \text{ using S.H.P. (= 0.466 on H.P.)}$$

The Wake System of Automatic Steering

By R. H. Rogers*

SHIP and its cargo weighing twenty thousand tons and moving twenty feet per second is reluctant to change its direction of motion, but is singularly free to yaw to port and starboard of the course being made good, as indicated by the wake. The sweep effect of the rudder is negligible hence the power to change a ship's heading, which is one thing, and to change her course, which is another, does not come from the rudder motive power, but from the stored energy of the moving mass and that necessarily at a sacrifice of its velocity.

The compass is a little slow in its warning and the helm is moved too late, too much and too often, with the result that a ship's daily run is the average of an undulating speed curve which has a dip for every helm movement. The General Electric Company has made observations and records for several years on many ships which reveal preventable losses of considerable magnitude as compared with other shipboard losses that are receiving much more attention.

The frequency and amplitude of yawing in a well trimmed ship of 12,000 tons displacement making 12½ knots in fair

Fig. 1.—Typical Yawing Chart Made by Hand Steering

sea and weather is shown in Fig. 1. This record was on a 300 degree course steered by hand to a gyro compass through a hydraulic telemotor and an electric steering gear, all in good condition. There were 67 reversals of headings in one hour. A yawing of 6 degrees in one half minute was noted. The ship yawed 4 degrees while going one length.

To mitigate the variable losses of time and fuel and to hold the ship closely to the desired course, are the functions of automatic steering devices which must kill incipient swings before they have grown appreciably.

OPERATING PRINCIPLES OF WAKE SYSTEM

The wake system of automatic steering functions to fix the course made good, leaving the ship's heading free to prevent deviations that might be caused by wind, seas or propeller drift. The actuating member is a taut wire line from the ship to a suitable drag, towed in the wake and which is therefore exactly in line with the course being made good. The ship pivots about the inboard end of the wire, pressing one or the other of two electric switches against it. These switches control an electric telemotor which works parallel to the

*Marine Department, General Electric Company, Schenectady, N. Y.

normal telemotor and controls the steering gear to give prompt and proportional countering helms which die out to zero as the error dies out.

The point of attachment for the wire has a small athwart-ship movement imparted by a mechanical connection to the rudder stock. This movement serves to allow the ship to take any heading necessary to free the switches from the wire, thus holding the direction of motion to a definite line. This lateral motion is too small to affect the direction of the long wire but it has a marked effect in the short distance

Fig. 2.—Diagram of Wake System Controls

to the switches where 1 degree of swing causes $\frac{1}{2}$ inch of relative movement.

Fig. 2 shows a schematic diagram of an application to a ship. It has been demonstrated that 145 fathoms of sounding wire towing a 30 pound sounding lead makes a satisfactory combination. The tension is 150 pounds at $12\frac{1}{2}$ knots, giving great rigidity against the side pressure of the switches. Rolling and pitching produce no detrimental relative movement between the wire and switches which may be adjusted for a reasonable tolerance. Fig. 2 shows the ship under very variable conditions following its predetermined course with free headings.

The practical operation of the wake automatic steerer is very simple and easily understood. The quartermaster will steer by hand on whatever heading is necessary to make good the desired course, the lee-way, if any, being indicated in

degrees at the wire. When satisfied with the course, the pilot house switch is closed, thereby putting the automatic in charge. The ship will now progress in a straight line but with variable headings if the deflecting influences are variable and the navigator is no longer required to estimate corrections for drift, etc. After a time, an appreciable error may be built up which may be corrected by opening the pilot house switch to allow of hand steering again for a few moments.

The guiding principle of the towed line is very marked, its indications being instantaneous and exact, being in advance of and in excess of those shown by the compass.

BRITISH TANKER DELIVERED.—The *British Fusilier*, which has been built and engined by Swan, Hunter & Wigham Richardson, Ltd., at their Neptune Works, Newcastle-on-Tyne, to the order of the British Tanker Company, Ltd., of London, has completed a very successful trial trip off the Tyne, and sailed to take up her station on her owners' service. The steamer is an oil tanker, carrying over 10,000 tons of oil, and is about 455 feet in length by 57 feet beam. The propelling machinery has also been constructed by Swan, Hunter & Wigham Richardson, Ltd., at their Neptune Engine Works, Newcastle-on-Tyne, and consists of a set of turbines of the Metropolitan-Vickers Rateau type, with double reduction gearing of the three-box floating frame type, steam being supplied by three large boilers fitted with Howden's system of forced draft, and burning oil fuel on the Wallsend-Howden system. The principal engine room auxiliaries are electrically driven. On the trials a speed of $11\frac{3}{4}$ knots was attained.

CABLE STEAMER DICKENSON LAUNCHED.—The cable supply steamer *Dickenson*, described on page 92 of our February issue, was successfully launched on February 17, at the yard of the Sun Shipbuilding Company, Chester, Pa., the sponsor being Miss Mary Dickenson, daughter of one of the former officials of the Commercial Pacific Cable Company, for whom this vessel is being built. The *Dickenson* was designed by Messrs. Cox & Stevens, who also superintended her construction, and as soon as she is completed will proceed to the Pacific Coast and take up her station at Midway Island, which will be her headquarters.

Fig. 3.—Comparison of Wake System of Steering and Automatic Steering by Compass Direction

Wood Preservatives For Shipbuilding Purposes

By Horace Holden Thayer*

Continuation of a series of articles containing information regarding shipbuilding materials and their uses that is not readily obtainable from shipbuilding handbooks and other generally available sources. The articles are not intended to be a complete exposition of the subject but will be found to contain items of value to the various classes of workers in this field who have to deal with these materials from the materials' point of view.

THIS article has to do with materials used during the construction of wooden vessels in order to guard against decay. The nature of this decay and the importance of guarding against it have been dealt with in the article by the writer on "Timbers and Lumber," in the September, 1921, issue of this magazine. The use of wood preservatives for the prevention of teredo attack will be considered under the heading of Protective Coatings for that purpose.

Good ventilation is one of the best safeguards against decay and provisions for it called for by the best practice are well worth while. On the other hand, the painting of inside surfaces of wood hulls, which is sometimes called for, retards the drying out of the wood and encourages decay.

SALT AND CREOSOTE

Probably the oldest preservative in use, and certainly the one in almost exclusive use up to comparatively recent years, is common salt. The salting of a vessel is done after the timbers to be preserved are in place in the vessel. Inaccessible spaces whose surfaces are particularly subject to decay are packed with salt, and this in most locations necessitates the fitting of boards, called salt stops, between the timbers to keep the salt in place. The salt when kept wet forms a preservative brine.

The only rival of salting whose value has been proved to date is coal-tar creosote, and this product either under its own name or some proprietary name has been extensively used during recent years. The nature of this material and its method of application may be understood from the following specifications which were adopted by the United States Shipping Board Emergency Fleet Corporation, which made this preservative the standard for its entire fleet of wood steamships and schooner barges. The specifications for the creosote oil itself were prepared by the Forest Service of the United States Department of Agriculture, which has done a great amount of research and other work on this subject. The high boiling point oil is specified to minimize the loss due to evaporation of the oil.

CREOSOTE OIL FOR BRUSH TREATING OF SHIP TIMBERS

1. The oil to be obtained from coal gas or coke-oven tar and shall be free from any tar, including coal gas tar and coke-oven tar, oil or residue obtained from petroleum or any other source. Oil to comply with the following requirements:

1. To be completely liquid at 15 degrees C.
2. To contain not more than 2 percent of water.
3. To contain not more than 0.5 percent of matter insoluble in benzol.
4. The specific gravity of the oil at 15 degrees/15.5 degrees C. shall not be less than 1.08.
5. The distillate based on water-free oil to be within the following limits:
Up to 210 degrees C. not more than 1 percent.
Up to 235 degrees C. not more than 10 percent.

6. The specific gravity of the fraction between 235 degrees C. and 315 degrees C. to be not less than 1.03 at 38 degrees/15.5 degrees C. The specific gravity of the fraction between 315 de-

grees C. and 355 degrees C shall not be less than 1.10 at 38 degrees/15.5 degrees C.

7. The residue above 355 degrees, if it exceeds 5 percent, shall have a float-test of not more than 50 seconds at 70 degrees C.

8. The oil to yield not more than 2 percent coke residue.

9. The foregoing tests shall be made in accordance with the standard methods of the American Wood Preservers' Association.

2. Although the brush treatment is less efficient than the pressure or open tank system, it is recognized as often desirable and is used by many in the absence of more thorough methods. Unless absolutely unavoidable the timber should not be treated when it is green, wet or frozen. It should be borne in mind that by not properly carrying out the brush treatment it is an easy matter to render the treatment worthless.

3. Coal-tar creosote oil should be applied with a three or four knot rubber set or wire bound roofing brush, the oil having been heated to a temperature of 200 degrees Fahrenheit. All crevices and shakes should be filled with the oil, using the same liberally for the first coat. The second coat should not be applied until the preceding coat has been fully absorbed. It is best to apply the different coats on different days.

4. During the building of hulls all faying or joined surfaces of timbers and planks, etc., throughout will receive two coats of preservative.

In a consideration of the relative merits of the salting and creosoting methods, it can be said for salting that it is inexpensive, easy to apply regardless of temperature and weather conditions, and comparatively easy to keep in condition or renew. Its chief objection is its weight and the loss of dead-weight carrying capacity thereby incurred. As its poisoning property is very low it must be used freely. It was estimated that one of the Emergency Fleet Corporation standard wood steamships would require about 90 tons of salt, if this method should be adopted. Salting also interferes with ventilation which particularly affects the spaces below the salt chocks, and it subjects iron fastenings, even when galvanized, to rapid corrosion.

The Forest Service has stated that coal-tar creosote is probably the most effective preservative which can be readily applied on ships at the time they are under construction. It has been thoroughly tried out and found to accomplish the desired results. There are proprietary preservatives made from wood tar and water gas tar which may be effective, but the writer does not know that any of them have been thoroughly proved. They have not to date been looked upon with favor by the classification societies. It is, however, claimed by one of the manufacturers of wood-tar creosote that such a creosote is much superior to the coal-tar creosote in locations where the wood is continually wet. Creosote is more difficult to apply properly, and this difficulty assumes importance when the timbers are green, wet or frozen; and the checking up of its proper application is more difficult. Workmen, except negroes, are subject to burns from it, particularly those with light complexions; but this can be guarded against by the use of vaseline. Oil paint cannot be successfully applied to creosoted surfaces and the creosote has a tendency to disintegrate oakum. It is claimed by some

*Member of the firm of Rossell & Thayer, naval architects and marine engineers, Philadelphia, Pa.

that the odors given off by creosote damage such cargoes as flour and rice, but the amount called for to meet classification society requirements is not sufficient to cause material damage of this nature.

The classification societies strongly recommend the use of a preservative during the construction of a wood vessel and the application of a preservative according to their requirements entitles the vessel to a longer classed life. Their requirements when salting is used are pretty definitely defined in their published rules for wood ship construction; but these rules do not cover the creosoting method and in some cases a classification society may require salting in whole or in part. As has been pointed out in the article on "Timbers and Lumber" before referred to, the hardwoods contain considerably more moisture than softwoods and therefore require a longer time to season. In vessels with oak framing the timbers might be far from being seasoned when in place in the vessel, whereas the framing, if of yellow pine or Douglas fir, would in the same length of time be well seasoned. For this reason one or more of the classification societies have in some cases required salting with hardwood framing.

DETAILS OF APPLICATION

The Forest Service has presented the following old classification society rules, somewhat modified, as representative of thorough treatment when the salting preservative method is adopted:

The stops between the frames to be placed at the light waterline, and the spaces between the frames filled with salt to the planksheer. If the frame timbers are choked apart, the chocks are to be partially split out next the ceiling, and the salt admitted to stops between the timbers of each frame, at the height of the light waterline, fore and aft, and the spaces filled with salt to the gunwale. The salt between the frames should be dampened down at intervals to renew the pickle.

The stern frame, and the cant frames, forward and aft, to be salted in the same manner down to the deadwoods and as many more frames as the cants, at each end, to be salted down to the short floor-heads, stops being put in at intervals of about three feet each. The spaces over the shelf or knees to be filled with salt, at least one inch deep. Stops to be fitted to keep the salt from choking the air and water courses, wherever these interfere with continuous filling.

After the ceiling is worked, holes of the size of treenails, to be bored in the middle of the strakes, and alternately into each timber of the frame nearly to the planking, and filled with salt, wetted with pickle and plugged. Where holes are bored for through treenails, if plugs are inserted to hold the brine, the frame may be salted and pickled thoroughly, before the fastening is all driven.

The ends of beams, arms of knees, hooks, transoms, stern-post, apron, and stem, the deadwoods and keelsons to be internally salted, in the same way. Holes to be also bored through the rail into the stanchion heads, the knightheads, head of pall-post, rudder-stock, bowsprit and masts, and the overhead arches of steam vessels for the reception of salt and brine, and be plugged for convenient renewal annually. The keelson to be cased fore and aft, where single, with room of one inch on top and sides for the reception of salt. If the keelsons are double, the space between to be ceiled and calked, and the salt put between them and covered.

The deck framing to be grooved along the grain, in the middle of the beams, ledges, carlins and partners, to the depth of an inch, and the grooves filled with salt as the deck is laid. The deck to be bored over the middle of the beams and ledges, in the middle of alternate strakes, salted and brined to the depth of six inches, and the holes tightly plugged one inch deep. The planksheer to be bored over the salt spaces for renewing the salt between the timbers. All salt plugs to be removable, that the salting may be renewed annually, until no longer necessary for the preservation of the wood.

As a guide to what may be called for when creosoting is adopted, the requirements of the American Bureau of Shipping issued in 1917 for the wood ships of the Emergency Fleet Corporation are of value. They called for two coats of preservative on the surfaces of all important structural members in contact with other surfaces, but not including calking seams or butts, and on all surfaces of beam ends for 4 feet 6 inches in from the ends, and three coats of preservative on all surfaces of beams in coal bunkers. Oak

treenails were required to be immersed in preservative heated to 180 degrees for at least ten minutes. Iron fastenings and spikes might be dipped in cold preservative, in lieu of grease, before driving, except where driven from surfaces which were later to receive lead and oil paint.

The coating of butts except in way of calking is particularly important, as decay is likely to begin at the butts. It is desirable to coat the exposed surfaces of all frame timbers as well as the faying surfaces; and also the frame side of the planking and ceiling. Other important surfaces are the tops of weather deck beams, contact surfaces of shelves, clamps and waterways, all contact surfaces of bulkheads and all parts of the deadwoods.

In order to be effective, the preservative should thoroughly impregnate the wood to a depth sufficient to allow for subsequent season checking, mechanical abrasion, injuries, etc. Creosoting by the pressure method is of course the best method, but this is usually not practicable for shipbuilding work. The next best method is dipping. A liberal application of hot creosote with an air spray or brush comes next in order to dipping, the air spray being probably the better of the two. With brush treatment the creosote should be flowed on, using a large brush, and not be handled like a paint. It is of little value to creosote timber before it is cut to size and shape because the subsequent cutting operations will even with the most thoroughly impregnated treatment penetrate the treatment and permit decay to start on the untreated wood thus exposed.

Creosote is much more effective when applied hot and the heating of it can be readily accomplished by the use of steam without fire risk or appreciable additional labor cost. A method of heating the creosote adopted by one shipyard was observed and reported upon by the Forest Service as follows:

A box about 2 feet wide and 10 feet long is made watertight by calking. The top is made with round holes cut into it, of the right size to receive a cone-shaped bucket. The lower part of the bucket sinks into the water, the top rim sitting over the hole, which holds the bucket in place. The box is filled with water which is heated to the boiling point by steam from a steam pipe at one end. This could also be accomplished by a steam coil, thereby saving the steam, or by a pipe running the full length of the box with jets at various intervals. Where possible, exhaust steam should be used. The wood preservative is placed in the cone-shaped buckets which, when set in the holes of the box, are immersed in the boiling water. The preservative soon heats to approximately the boiling point of water and is taken in the buckets directly to the ships, to be applied on the timbers. Before this method was in use four men in different parts of the yard at wages of 40 cents an hour were employed to heat this preservative. With this method no extra men are necessary as the men applying the preservative, on returning to the box simply refill their empty buckets, place them in the hot water, and take one filled with hot preservative. When not in use the buckets should be covered. The preservative thus is heating while the men are applying it on the ship timbers. In this manner a saving of about \$17 a day was accomplished, beside keeping the preservative at a high temperature continuously, with no risk of fire.

OTHER PRESERVATIVES

Brazilians are said to use a preservative called "Gallagalla," composed of pitch, unslacked lime and oil, mixed to a rather stiff consistency and applied without heating. A process for treating the wood with a solution of hot ferrous sulphate followed by a solution of copper sulphate was investigated by the Forest Service, and an adverse report submitted by them. There is a poisoned paraffine process which is claimed by its inventor to provide efficient protection at a cost only slightly in excess of creosoting. There are also other processes proposed from time to time for the preservation of ship timbers from decay, but they are generally too expensive or are impracticable under shipbuilding conditions.

THE NATIONAL SAFETY COUNCIL has accepted the invitation of the Buffalo Chamber of Commerce to hold the 1923 National Safety Congress at the Statler Hotel, Buffalo, N. Y., October 1 to 5.

Waves of the Ocean

Theory of Waves—Speed, Length and Height — Surface Tension

By C. H. Peabody, Dr. Eng.

IT is astonishing how little is known about the waves of the ocean considering that they have been known to navigators for thousands of years, more especially as the commonly accepted theory was developed by Gerstner more than a 100 years ago. To be sure the true ocean wave is found only in the open sea and scientists habitually live ashore; few seamen are scientists and those who are have something else to do than making investigations of the shifting and evanescent waves; and wave measurements are difficult and uncertain.

TROCHOIDAL THEORY OF WAVES

The commonly accepted theory is known as the trochoidal theory, which has the advantage that it gives fairly simple methods of calculating the properties of waves and ties in fairly well with the measurements of waves that have been made, namely of length and speed. As for the somewhat formidable name of the theory it may be sufficient to say that the trochoid is the path of a spot on a wheel as it rolls

Fig. 1

along, as illustrated in Fig. 1; such a trochoid is upside down when compared with that of the wave but that need not concern us now.

If you watch a wave at sea you will see it approach the ship, under-run it and speed away in the distance; but if you watch something afloat, perhaps a bit of seaweed, you will see it move up and down with the wave but you will see that it does not move forward with the wave. A close inspection shows that it moves back and forth as well as up and down. Usually there is a slow drift in the direction of the motion of the wave, but some time is required to detect it and one is likely to assume that it is blown along by the wind; and so it undoubtedly is though there is reason to think there is a proper drift.

TROCHOIDAL MOTION

Starting with the idea that a particle of water affected by a wave moves up and down and back and forth, the easiest conception of such a motion is that the particle of water revolves round in a circle about a fixed center. That is the

Fig. 2

fundamental idea of trochoidal motion. Thus in Fig. 2 let $a b c d e$ be particles of water uniformly spaced; let c be at the crest of the wave and let a and e be at hollows, while b and d are on the slopes; a curve drawn through these points is a trochoid like that of Fig. 1 except that it is the other side up.

The real reason why the trochoid was shown by Gerstner for his wave theory, is that it is relatively easy mathematically; when he found that with the theory he could compute the properties of the waves and that his computations tied in with what was known or could really be determined about waves, he must have been convinced that he had found the true key to the problem.

But it is easy to show that the sea wave does not have the

Fig. 3

form of a trochoid because the mathematical limit of that wave is found when the trochoid of Fig. 1 is made by a point on the extreme outside of the tire. Thus in Fig. 3 when the radius of the orbit of a particle of water is taken as

6.283

of the length we have a cycloid. The trochoidal theory shows that a particle of water might revolve in such orbits as shown in Fig. 3 and that at the crest the pull of gravity would be just sufficient to keep the particle in its orbit and no more. Should the height of the wave increase ever so little the particle at the crest would fly off and the wave would break. But the most casual observation of waves at sea shows that they break at the crest long before they become so high. The cycloidal wave, should one exist, would have a height from hollow to crest of nearly a third of the length, whereas sea waves break when the height is a fifth of the length or less.

REQUIREMENTS FOR FORMATION OF SEA WAVE

Now mathematicians have decided that while a trochoidal wave could exist, if once made, such a wave never has been or can be formed at sea. There are three things necessary for the formation of a sea wave, namely, equilibrium, continuity and irrotation. This looks like a formidable list of requirements and the equations expressing them are even more formidable to the dabbler in mathematics who knows about enough to integrate for the area of a simple figure. But the fundamental ideas can be stated simply enough.

For the trochoidal theory we have assumed that each particle of water revolves uniformly in a circular orbit; the forces acting on it are in equilibrium as are those acting on a planet; the earth swings round securely forever in its orbit. A similar, though perhaps a more complicated, condition is required for any wave motion.

The condition of continuity is almost ridiculous in its simplicity; there must not be any holes in the water; a lot of bubbles for example.

The third condition requires a little more explanation. Consider the crank of an automobile; if the handle is a solid piece of steel it will turn in the hand, and the motion of the handle in its orbit will be rotational; but if there is a loose wooden handle it will not turn in the hand, and the same side will always be on the top, and so its motion is irrotational. The only test for rotation of the water in a trochoidal wave is that the equations for the wave do not conform to the tests applied by the mathematician; as

we are not going to develop those equations nor explain the test we will have to let it go at that. But this we will say that the only forces acting on the water in a wave are pressure and gravity, and the mathematician readily shows that those forces cannot produce rotation. If, then, there can be no rotation to a sea wave, the trochoidal wave with rotation is not the true sea wave. Q.E.D.

There are one or two little matters which have been left out all along, like viscosity of the water and surface tension or, as it is sometimes called, capillarity. It is easy to show mathematically that these influences have no appreciable effect on sea waves which commonly are three hundred feet long and sometimes are a thousand feet long.

IRROTATIONAL WAVE THEORY

By the application of the methods of hydrodynamics, Sir G. Stokes has developed the theory of an irrotational wave which has two items of interest for us; one is that the form of the wave at the limit when the crest begins to break is reasonably like that of the great sea combers; the other one is that his theory gives forms for long gentle swells that approach near to those of the trochoidal wave. The last item is very important for it indicates that for waves that

Fig. 4

do not approach the limit of breaking, we may use the methods of computation developed for the trochoidal wave.

The form of Stokes' wave at the limit is shown by Fig. 4, taken from the writer's "Naval Architecture;" so far as is known that is the only correct representation of Stokes' wave extant. The most notable thing about the contour of the wave as shown in Fig. 4 is the roof shape of the crest; the angle at the peak is 120 degrees and that is shown by Stokes to be a necessary condition for an irrotational wave. Even casual observation of sea waves which have a tendency to break at the crest will show that they have this characteristic.

It has already been said that a rotational wave like the trochoidal wave (which conforms by the way to the requirements of equilibrium and continuity) is discarded by the mathematicians because there is no natural cause to make rotation. Curiously enough attempts to make artificial trochoidal waves do not come out any better. When R. E. Froude wanted a trochoidal wave in the Admiralty experimental tank and set up a proper apparatus for that purpose, he did not get it, but got a wave similar to the Stokes wave as he kindly showed the writer when he visited that tank.

One more feature of the Stokes' wave will be mentioned and then we will drop it as it is not conveniently computed for ordinary use; this feature is that his wave is shown mathematically to have a slow drift of the water in the direction in which the wave runs. Another mathematical form possible for irrotational waves is proposed by Michell; its notable feature is that the theory shows that the crest will break when the height is one-seventh of the length. It also approaches the form of the trochoidal wave when the height is small.

RELATION OF SPEED AND LENGTH

The most interesting property that can be computed by aid of the trochoidal theory is the relation of speed and length; without going into details of the theory or its application for this purpose we will give the results in the following table:

Length, Time and Speed of Waves

Length, feet	Time, seconds	Speed, feet per second	Speed in knots
50	3.10	16.0	9.5
100	4.40	22.7	13.4
200	6.20	32.0	19.0
400	8.80	45.3	26.8
600	10.80	55.0	32.8
800	12.50	64.1	37.9
1,000	14.00	71.6	42.4
2,000	19.8	101.5	60.0

It may be interesting to note that the open ocean wave is about 400 feet long and has a speed of 26.8 knots, a speed attained by a few classes of ships such as express passenger steamers, battle cruisers and destroyers; a thousand-foot wave has the speed of an express train and a 2,000-foot wave is twice as fast as anything that floats.

The measurements of the time and length of waves can be made without special apparatus and require but little practice; unfortunately conditions for good results are likely to interfere with the proper navigation of the ship, which is the reason such measurements are so seldom undertaken.

HOW TO MEASURE LENGTH AND TIME OF WAVES

When a ship is steaming directly across the waves, a life buoy may be run out on a log line, which has marks at every 50.7 feet. By trial the length of the line may be adjusted so that the buoy shall be on the crest of a wave astern at the time when there is a crest directly under the observer.

For measuring time it is most convenient to stop the engine and wait till the ship has lost way, and then note the time between successive crests. If, however, it is desired to take observations while the ship is steaming slowly against the waves an allowance must be made for the speed of the ship. Suppose that the ship is steaming ten knots an hour, then since there are 6,080 feet in a knot the speed in feet per second will be:

$$10(6,080 \div 3,600) = 10 \times 1.69 = 16.9 \text{ feet per second.}$$

If the observed time from one wave to the next wave is 6.4 seconds the ship will have run forward

$$6.4 \times 16.9 = 108 \text{ feet}$$

during the time of the observation. If the observed length of the wave is 400 feet it is clear that the crest will have run only

$$400 - 108 = 292 \text{ feet.}$$

Consequently a simple proportion will give for the time required to run 400 feet

$$292:400 :: 6.4:t_w, \text{ therefore } t_w = 8.8 \text{ seconds.}$$

HEIGHT OF WAVES

There is nothing more illusive than the apparent height of waves, especially when the ship is rolling and the waves are high and threatening. No apparatus is necessary and there is no need to change the course or speed of the ship; all deck officers are advised to acquire some facility in estimating wave heights. The observer must find by trial some position at a proper height, such that he can just see the horizon over the crest of the nearest wave when the ship is erect in a hollow. The distance from his eye to the water is the height of the wave from hollow to crest. Patience and adroitness will be required by the observer to get a combination of the conditions so briefly stated above; and it may be difficult to find a proper location on ships with lofty decks now in common service. Wave heights are seldom more than five percent of the length; so that a 400 foot wave would be 20 feet high.

EFFECT OF DEPTH OF WATER ON WAVES

Any acceptable wave theory must indicate that the wave disturbance dies out downward and agree with the observa-

tion that there is little or no disturbance in deep water. The trochoidal theory gives the following table:

Decrease of Wave Disturbance with Depth	
Ratio of depth to length	Ratio of orbits of particles
0.01	0.94
0.02	0.88
0.03	0.83
0.04	0.78
0.05	0.73
0.1	0.53
0.2	0.28
0.3	0.15
0.5	0.043
1.0	0.0019
2.0	0.000035

It will be noted that at a depth equal to one-tenth of the length the disturbance is only half that at the surface; a 400-foot wave may have a height of 20 feet at the surface but at a depth of 40 feet below the surface the disturbance is only 10 feet. At a depth equal to half the wave length the disturbance is reduced to four percent that at the surface. Our 400-foot wave with a height of 20 feet will have a disturbance of only five inches at a depth of 200 feet. This is the rational of the rule that the depth of water proper for speed trials of a ship is half the corresponding wave length. Thus a ship with a speed of 26.8 knots will be accompanied by waves 400 feet long and should not be tried in less than 200 feet of water. More extended observations of speed trial conditions show that this rule is likely to give greater depth than necessary for fast ships like torpedo boats and destroyers and not enough for large ships with deep draft.

ENERGY IN WAVES

Viewing waves either from the shore or from the deck of a ship at sea one is impressed by the limitless store of energy running to waste. The theory of trochoidal waves gives a simple approximate equation for energy

$$E = \frac{1}{8} w L h^2$$

where w is the weight of a cubic foot of water (64 pounds for sea water) L is the length from crest to crest in feet and h is the height of the wave also in feet; this gives the energy of a strip of water one foot wide and L feet long; the depth is not limited but it has already been shown that a wave dies out rapidly downward so that the energy is relatively near the surface, say half a wave length deep. For a wave 400 feet long and 20 feet high the equation gives

$$E = \frac{1}{8} \times 64 \times 400 \times 20^2 = 1,280,000 \text{ foot pounds.}$$

Were there any way of harvesting the energy of the sea there would be no occasion to worry over coal supply. But at present there seems better prospect of harvesting the sunbeams of the desert of Sahara.

EFFECT OF SURFACE TENSION

So far we have been dealing with large waves which are not affected by surface tension or capillarity. Our present interest is that surface tension interferes if we try to make observations on small waves either in the laboratory or on open water, observations which are attractive and relatively easy but which give incorrect impressions, if our results are applied to large waves. If the waves are small enough their characteristics are controlled entirely by surface tension, gravity having no appreciable effect. To show that the characteristics are different from those of large waves it is enough to say that the shorter such waves are the faster they go. This is exhibited in the following table which is in inches and seconds.

Wave length	Speed	Frequency
0.20	12	61
0.04	27	680
0.02	38	1,930

Since large waves increase in speed as they grow longer while surface tension waves decrease in speed, there must be some minimum speed for little waves, little enough to feel the effect of both surface tension and gravity. The theory shows that such a wave would be 0.68 inch long and that it would have a speed of 0.76 feet per second or 0.45 of a sea mile per hour. This result agrees with an observation by Scott Russell that a wind with a velocity of half a mile an hour can start a ripple on the surface of still water; this ripple soon disappears if the wind dies down. The same observer says that true waves appear when the wind has a velocity of two miles an hour, which is the speed of trochoidal waves 2.2 feet long.

The writer once tried to determine how long ship's models for the towing tank should be to avoid capillary interference with wave formation in the wake of the model. Assuming that such effect should be less than one percent, the minimum speed of the model was computed to be 0.78 knot. Now models are tested at what corresponds to full speed and at fractions of that speed. If we assume that a model may be tested at quarter speed, then the full model speed should not be less than three knots. The law of similarity shows that, if a model of the ship is 12 feet long and the ship is 588 feet long, the full speeds of the ship and the model will be twenty-one and three knots respectively. This falls in with customary practice. The size of models is determined by other matters, such as convenience in measuring and recording results in the model towing basins. At the Washington model basin and at one or two others models twenty feet long have been used; at the greater number of experimental stations the models have been about twelve feet long and this is probably the minimum length for best practical results.

Turbine Governor Enables S. S. Mount Carroll to Maintain Speed in Record-Breaking Storm

DURING the very severe storms that swept the Atlantic during the early part of January of this year, many vessels, embarrassed by racing propellers, were compelled to proceed at reduced speeds; but the S. S. *Mount*

Operating Mechanism of Oil-Type Governor Mounted at Rear of Maneuvering-Valve Chest

Carroll of the United American Lines was able to maintain her regular 13 knots through the worst of the blow and had the pleasure of passing many liners that under ordinary

Strength of Column-Supported Foundations

Analysis of Stresses in Various Parts of Condenser Foundation, Assuming Maximum Inclination of Ship

By John Flodin

TO illustrate the principles underlying the strength calculations for high, column-supported foundations, the condenser foundations shown in Fig. 1 will be considered. This construction is worthy of particular attention partly because of the height of the structure, which is due to the necessity of placing other auxiliary machinery below the

ingly large fiber stress, say about 17,000 pounds per square inch.

STRESS ANALYSIS

When the ship is in the upright position the columns will act in compression, if they are "short"; otherwise the bend-

Fig. 1

condensers, and partly because of the size of the condensers, it being estimated that the wet weight of each condenser plus one-half of the weight of the connecting exhaust trunk equals 124,000 pounds.

It is not the object here to attempt an exact determination of the loads on the foundations due to the above weight, but rather to analyze the stresses in the various parts of the foundation structure, assuming that the loads have been determined with a satisfactory degree of accuracy. For our purposes we may, then, omit all dynamic considerations and as a rough but safe approximation assume a maximum inclination of the ship, both in the transverse and in the fore-and-aft direction, of 90 degrees. The error thus introduced may readily be compensated for by allowing a correspond-

ing stresses they are subjected to may be calculated in the ordinary manner by means of any of the well-known formulæ. In this connection it should be noted that the centers of the condensers are not vertically above the centers of the foundations, so that the distribution of the loads on the frames forming the ends and sides of the foundations is inversely proportional to the distances of the horizontal projection of the center of gravity of each condenser from the frames supporting that condenser, which also applies when the ship is inclined. These partial loads, designated R in the following, are indicated in Fig. 1 together with the distances from the projections of the centers of the condensers to the sectional centers of gravity of the foundation frames. For estimating column loads when the ship is in the upright

position, this breaking-up process must, of course, be carried one step further.

When the ship is inclined, each frame (i.e., two columns and their connecting overhead girder) may now be regarded independently of the rest of the structure and the stresses analyzed. From Fig. 2 we see at once that there is direct shear in the columns, but since this stress may be found in the ordinary manner no attention will be given to it here. It will also be seen that a tipping moment LR is set up, tending to tear the foundation away from the ship's struc-

Fig. 2

ture, and that a further moment $L'R$ causes tension in the upper column in Fig. 2 and compression in the lower column. The former moment we shall neglect in this discussion since it is external to the foundation itself, but the latter moment, $L'R$, introduces stresses within the foundation, which are not negligible. This moment is resisted by the moment Fd , where F is the tension or compression in the column and d is the distance between the sectional centers of gravity of the columns. We may then write

$$F = \frac{L'R}{d} \dots\dots\dots (1)$$

This is not, however, the total stress in either column, since each frame acts as a cantilever as indicated by full

Fig. 4

lines in Fig. 3. If the upper or free ends of the two columns are rigidly connected by means of a girder, those ends are bound to move together, and to move in such a manner that

they will always remain parallel to their initial positions. We have, in other words, a case of cantilevers with constraint which resembles very closely the condition often found in bridge portals under wind load. Retaining the condition that the free ends of the cantilevers must deflect so as to remain parallel to the initial position, we may, for convenience, discard the connecting girder and say that each cantilever (or column) carries such a part P of the total load R on the foundation frame, that both cantilevers deflect an equal amount. Either cantilever is then represented by Fig. 4, where l is the free length. The bending moment of this cantilever is zero at the point of contraflexure (i.e., at the half-length, if the column is of uniform section) and is maximum at either end, where

$$M = \frac{1}{2} Pl \dots\dots\dots (2)^*$$

The total fiber stress in any column may now be found by combining the results from formulæ (2) and (3), both quantities being expressed in pounds per square inch. In lieu of the rather cumbersome process of combining direct tension or direct compression with the tension or compression due to bending, sums obtained by simple addition may be accepted as sufficiently accurate except where the sum of the compressive stresses approaches the maximum allowable unit stress to within, say, 5 percent.

Obviously we are justified in considering the columns as cantilevers with constraint only in case the conditions of rigidity at the bases of the columns and at the connections to the overhead girders are satisfied, and provided the overhead girder is rigid enough to prevent appreciable deflection of the kind shown by dot-and-dash lines in Fig. 3. The first two of these requirements are taken care of by filleting corners or by taking the free lengths of the columns as extending well into the brackets, as conditions may dictate; but the last named prerequisite for the use of formula (2) requires more careful consideration since it means that bending stresses are set up in the horizontal overhead girder.

The magnitude of these stresses may be determined from the following: As indicated in Fig. 3, points of contraflexure occur at the mid-length of the columns, while the

bending moment at the ends of the columns is $\frac{1}{2} Pl$, which

is the moment formula for a free-ended cantilever of one-half the length of the cantilever with constraint. This means that we may regard the columns as cut at the points of contraflexure and apply the loads P at the free ends thus obtained, without changing the values of the moments. It is now readily seen that the bending moment in the overhead girder becomes

$$M' = \frac{1}{2} Pl' \dots\dots\dots (3)$$

where l' is the distance from the point of contra-flexure in the column to the sectional center of gravity of the overhead girder, as shown in Fig. 3. It must be borne in mind, however, that if the columns of any one foundation frame are not of equal section, the magnitude of P will vary in direct proportion to the section moduli of the columns, and the larger value for P must, of course, be used in finding the bending moment in the girder for that frame.

It is not desired to give the impression that these bending formulæ will give satisfactory results regardless of the relative sizes of the columns. It is quite conceivable that, for example, the upper column in Fig. 3 might be so light that it would fail in tension while the lower column deflected as

*See Merriman, Mechanics of Materials, Article 65, page 163, 10th Edition.

a free-ended cantilever and the overhead girder remained straight. In such a case the bending moment in the overhead girder may be expressed by $M' = F'd$, where M' is the moment found from (3) and d is the distance between centers of columns. Then $F' = M'/d =$ the tension the upper column must sustain in order to cause the overhead

girder to deflect so that the lower column may act as a cantilever with constraint. From this consideration it is seen that formula (2) becomes inapplicable, if there is too great variation in the section moduli of the four columns of either foundation, unless the fiber stresses are kept correspondingly low.

The Duties of a Marine Superintendent

The marine superintendent of a steamship company is looked upon by many as an individual who has been able, by some means, to obtain one of the most desirable positions in the gift of a ship operating company. A general idea prevails that he looks after the upkeep of the company's fleet but the details of just what he is supposed to do are not so generally known. The following is a brief outline of some of his duties as directly affecting the operation of a ship.

THE principal responsibility of the marine superintendent of a steamship company is to keep the company's vessels in fit condition to meet their schedules and this keeps him continually moving in a maze of arrival dates, discharge dates, cargo cancellation dates, dates on loading berth and sailing dates. All repairs and alterations required must be arranged and undertaken so as not to interfere with the above dates.

This is a problem at all times as it is natural to endeavor to start loading as soon after discharge as possible. Hold repairs are, therefore, always urgent, the time allowed being limited, if possible, to the time necessary to clean the holds before again loading. In the case of engine room repairs there is more time but even here it is desirable to complete all work, or the major part of it, a couple of days before sailing in order to try out the machinery and have time to undertake contingencies that may develop.

Every job is therefore a rush job and, as excuses will not avail, should delay of the ship occur through uncompleted repairs, the marine superintendent must be forever in touch with his work to guard against those undertaking the repairs falling down on their completion dates.

VESSEL IS INSPECTED PROMPTLY UPON ARRIVAL

Upon the arrival of a ship the first thing done is to visit the vessel and look it over so far as possible (the holds naturally will be inaccessible) and determine the repairs necessary to maintain the vessel in proper operating condition. To assist in this and to save time, the captain and chief engineer should have repair lists ready that were prepared on the trip. These lists are of great value, if carefully prepared, and can be made the means of saving a great deal of time.

Contracts are then prepared and let for such work as is deemed necessary by the marine superintendent, the awards being made after consideration of bids submitted and the ability of the contractor to meet the completion dates required as determined by experience gained from previous work.

While the placing in hand and supervision of repairs during a vessel's stay in port are sufficient to keep the marine superintendent hustling, there are other duties which he must watch out for and which are liable to delay the vessel, if overlooked. Some of these are as follows:

PERIODICAL DRY DOCKING OF THE VESSELS

In order to obtain efficient operation of the vessel and conserve fuel it is customary to dry dock a passenger ship about every six months and a cargo ship about every eight months for routine examination of bottom, painting and overhauling of sea valves. In this connection he must also be sure to notify the United States Local Steamboat Inspectors,

as the law requires that such notification be made whenever a ship is placed on dry dock for repairs.

The United States Steamboat Inspection and the American Bureau of Shipping requirements are that tail shafts be drawn for examination every three years in the case of shafts fitted with solid liners and every two years where two short liners are fitted. The classification society and local inspectors are very prompt in following up the drawing of tail shafts and, unless a careful check is kept on these, an operator will be very likely to have his ship denied clearance until it has been dry docked and the tail shaft drawn for examination.

It is not always possible or necessary for a United States local inspector to attend every dry docking of a ship because of the irregular times at which dockings are made and the limited staff in the local office. The requirements of the law must be met, however, and the inspectors notified so that the dry docking will be covered, if the local office deems it necessary.

The same applies in the case of tail shafts. An earnest endeavor is made by the inspectors to cover each drawing of a tail shaft but an inspector has not the time to stand around several hours waiting for a shaft to be drawn and an operator cannot be expected reasonably to hold a ship on dry dock, with the tail shaft out, until an inspector can get there to examine it. The local office requires that a report be submitted, however, in all cases where a tail shaft has been drawn and an examination not made by a United States inspector.

This report must state the time and place of drawing and the condition of the shaft. In making this report, the marine superintendent has two alternatives. He may secure a certificate from the American Bureau of Shipping giving the report of their inspector (the American Bureau maintains resident or district inspectors so that it is possible for them to cover all cases) or he may secure an affidavit stating the condition of the shaft from the chief engineer of the vessel.

Either of the foregoing are acceptable to the United States local inspectors.

ANNUAL INSPECTION

The laws of the United States require that all vessels under the jurisdiction of the United States Steamboat Inspection Service be inspected annually and no vessel will be cleared from any port unless it has on board an unexpired certificate of inspection (except in a special case where a vessel whose certificate has expired is permitted to sail to another port for repairs, in which event, however, no passengers or freight are permitted to be carried en route).

It is therefore incumbent that the marine superintendent

keep informed at all times regarding the expiration dates of his ships' certificates and make arrangements for putting them through their annual inspections in time to allow for making such repairs as may be required by the United States local inspectors in time to secure new certificates before their scheduled sailing dates.

RE-CLASSIFICATION SURVEYS

Another date that must be kept in mind is the date the re-classification surveys required by the American Bureau of Shipping are due. These surveys are due at intervals of four years and must be carried out, if the vessel is to be retained in her class.

On account of the amount of work involved and in order to interfere as little as possible with the sailing schedule of the vessel, the American Bureau of Shipping allows one year for the carrying out of this survey.

It is in the interest of the owner, however, for the marine superintendent to put the vessel through her re-class survey as quickly as possible after it becomes due.

The following is a brief outline of the work necessary to put a vessel through a re-class survey:

DECK

1. Ship to be dry docked.
2. Bottom to be cleaned for examination.
3. Bottom to be painted with coat of anti-corrosive, one coat of anti-fouling.
4. Rudder to be lifted for examination of pintles and gudgeons.
5. The holds, between decks, peaks, bilges and the surface of the framing and plating to be cleaned, and also engine and boiler spaces and bunkers to be cleaned out.
6. Platform plates in engine and boiler room to be lifted.
7. In the holds, and bunkers, one strake of sheathing to be removed and strake of ceiling fore and aft and all portable hatches to be lifted.
8. Double bottom tanks to be thoroughly cleaned out, all ceilings to be lifted from tank tops, tanks to be tested with water pressure to the height of load line. Tank tops to be cleaned and coated with approved material and all ceilings re-laid.
9. Deep tanks, peaks, fresh water tanks and oil fuel tanks which form part of the structure of the vessel to be cleaned out and have water test of eight (8) feet above tank or the load line.
10. A steel plate one-half ($\frac{1}{2}$) inch thick to be fitted below sounding pipe so that rod will strike on it.
11. All parts of steering arrangement together with the blocks, rods or other transmission gear all to be opened up for examination.
12. Windlass and hand deck pumps to be stripped and opened up.
13. The sluice and watertight doors freed up and put in good working order.

NOTE: In oil tank vessels: All tanks cleaned and proven freed of gas. Each compartment and cofferdam to be tested with a head of water up to the top of the expansion trunk hatchways.

ENGINE

14. Tail shaft to be drawn. (Get record of last drawing.)
15. All cylinders, or turbines, pistons, valves, pumps, condensers, thrust blocks, main and tunnel bearings, shafting, evaporators and steam steering gear to be opened up for examination.
16. All valves on all manifolds running to double bottoms and bilges to be opened up for examinations, spindles, valves and seats left exposed.
17. All boilers and superheaters and all valves and mountings on all boilers to be opened up for examination, leaving valves, spindles, seats and springs exposed, which includes main and auxiliary stops, gage glass stops, test cocks, whistle stops, surface and bottom blows, safety valves, main and auxiliary feed checks and stops.
18. All main steam pipes, if of copper, to be annealed and tested by hydraulic pressure.
19. After examination all parts of whatever description that are passed by surveyor to be closed in good order as before.

The foregoing may be divided over several turn-arounds in which case the marine superintendent must keep in touch with the outstanding items to be put in hand on the vessel's return.

GRAIN FITTINGS

In all cases where a vessel is fitted for the carriage of grain it is necessary that a certificate approving the grain fittings be obtained from the Board of Underwriters. A clause is usually inserted in the grain fitting contract requiring the contractor installing the fittings to secure this certificate and deliver it to the ship.

Failure to obtain such a certificate is apt to delay a vessel's departure and is also likely to cause additional outlay of money, if a vessel is fitted for the carriage of grain in one port and proceeds to another port to load. Such a case recently came to the attention of the writer where a vessel was fitted for grain in a United States port and proceeded to Canada to load. Due to failure to obtain a certificate from the Board of Underwriters in the port where the grain fittings were installed the Canadian Underwriters (who would have recognized such a certificate had it been on board) demanded changes and additional work which equaled the cost of the original installation.

UNITED STATES SALVAGE ASSOCIATION

A comparatively new association which came into being during the World War, and which is assuming a position of importance in marine circles, is the United States Salvage Association. This association is covering a large number of vessels under American registry (all Shipping Board vessels are subject to their surveys), the principal object being to conduct inspections and make reports relative to the cargo carrying condition of a vessel.

Inasmuch as the Board of Underwriters accepts the reports of the United States Salvage Association and a favorable report is reflected in a reduction in insurance rates, it behooves a marine superintendent in charge of a ship subject to these inspections to see that any recommendations made are carried out.

CONCLUSION

In conclusion let it be noted that the position of a marine superintendent is one that requires the experience of an "old timer" in the marine game.

The men usually appointed to this work are former masters or chief engineers who have been thoroughly initiated into the mysteries of ship operation. That even such experienced men will have no time for non-essential work will be apparent from the foregoing outline of some of their more important duties.

Turbine Governor Enables S. S. Mount Carroll to Maintain Speed

(Continued from page 179)

circumstances could outdistance her. J. P. Stafford, chief engineer of the *Mount Carroll*, states that his hand-picked engine-room crew was chiefly responsible for this performance, but he also gives great credit to the governor, with which the *Mount Carroll's* Westinghouse turbine is equipped, because it kept the propellers at practically constant speed regardless of whether they were in the water or out of it.

This governor is of a new type which automatically keeps the turbines from racing when the vessel is light or when the screws come out of the water. The mechanism is not operated by steam in the usual manner, since deposits of dirt from the steam sometimes interfere with the extreme reliability of operation that is essential for a governor. Instead, oil under pressure, derived from the lubricating supply of the turbine, which is necessarily always available, is used; and the controlling pressure is maintained by a small centrifugal pump mounted on the turbine shaft. By this arrangement, the variations in the turbine speed vary the oil pressure directly and instantly.

Questions and Answers Relating to Naval Architecture and Marine Engineering

Conducted by James L. Bates, Naval Architect, and W. B. Newton, Marine Engineer

This department is maintained for the purpose of answering all questions relating to ships and their machinery. All inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

Boiler Requirements for Marine Engine

Q. (1186).—I have a letter from a company selling boilers, and they estimate my requirement to be 1,000 pounds steam per hour for a small marine engine. How do they know that the engine will require that amount of steam per hour, and what do they mean by 1,000 pounds per hour without giving boiler pressure?—Engineer.

A. (1186).—Unless the company was given such information relative to the engine to be served as indicated horsepower or dimensions, revolutions per minute and steam chest pressure, there seems to be no way of determining the amount of steam required. In the former case the pounds of steam per indicated horsepower per hour might have been assumed and then multiplied by the indicated horsepower. In the latter case the indicated horsepower might have been worked out from the dimensions and again the pounds of steam assumed and multiplied by the estimated indicated horsepower.

Mechanical Efficiency of a Two-Cycle Oil Engine

Q. (1189).—Please tell me what would be the probable efficiency of a Beardmore engine, two cycle, 200 brake horsepower, 300 revolutions per minute, marine engine with separate compressor. Would the efficiency be between 68 and 73 percent or would it be higher? V. C.

A. (1189).—The mechanical efficiency of the engine to which you refer would be, from the information given, about 70 percent.

Diameter of Engine Shaft

Q. (1191).—What size shaft should be installed for a 100 horsepower triple expansion engine, turning about 220 revolutions per minute?

A. (1191).—As the data given are insufficient for determining the crank shaft diameter, certain values have been assumed, where lacking, in order to solve the problem.

D = diameter of shaft in inches.
 F = maximum turning force.
 M = bending moment in inch pounds.
 $R. P. M.$ = revolutions per minute = 220.
 T = maximum twisting moment in inch pounds.
 T_1 = equivalent twisting moment in inch pounds.
 f = maximum allowed stress in pounds per square inch = 5,500.
 r = radius of crank in inches = 4 inches assumed.
 $I. H. P.$ = indicated horsepower = 100.
 k = a constant depending upon the number and arrangement of cranks = 1.32 (for three crank, triple expansion engines).
 L = distance between bearings + a certain distance inside the bearing, assumed as 7 inches + $(2 \times \frac{1}{4} \text{ inch}) = 7\frac{1}{2}$ inches.

$$T = \frac{I. H. P. \times k \times 63,024}{R. P. M.} = \frac{100 \times 1.32 \times 63,024}{220} = 37,810$$

$$F = \frac{T}{r} = \frac{37,810}{4} = 9,453.$$

$$M = \frac{F \times L}{8} = \frac{9,453 \times 7.5}{8} = 8,862$$

$$T_1 = M + \sqrt{M^2 + T^2} = 8,862 + \sqrt{(8,862)^2 + (37,810)^2} = 47,678$$

$$D = \sqrt[3]{\frac{5.1 \times T_1}{f}} = \sqrt[3]{\frac{5.1 \times 47,678}{5,500}} = 3.54 \text{ or } 3\frac{1}{2} \text{ inches.}$$

Piston Clearance—Engine Power Ratings

Q. (1191).—(1) What allowance should be made for clearance in piston and cylinder diameters?
 (2) What is the relation between the power ratings of steam reciprocating and oil engines?

A. (1191).—(1) The following differences between the diameter of a piston and the bore of a cylinder have been found satisfactory where solid or plug pistons have been used:

inches	Allowance, inches
To 4	0.002
To 8	0.003
To 12	0.006
To 16	0.008
To 24	0.011
To 28	0.012
To 34	0.015

(2) Oil and gas engine powers are based upon the power delivered by the shaft, known as brake horsepower while steam reciprocating engines are rated upon the power developed in the cylinders or indicated horsepower. The mechanical efficiency of the average reciprocating engine is about 92 percent; therefore, to put the two engines upon the same basis the oil engine would be developing 150 brake horsepower while the steam engine would have an output of $150 \times 0.92 = 138$ brake horsepower.

Safe Working Pressure of Scotch Boiler

Q. (1153).—Please give the formula showing how to find the safe working pressure of a double ended Scotch boiler, 16 feet 9 inches long and 6 feet diameter, with triple riveted longitudinal seams, thickness of plate 1.08 inches, tensile strength 54,000 pounds per square inch.

A. (1153).—Since insufficient data have been given in the question from which to make a specific calculation, it is assumed that the boiler has already been designed and that a method only for determining the safe working pressure is desired.

According to the General Rules and Regulations of the United States Steamboat Inspection Service the working steam pressure allowable for any dimension of boilers must be ascertained by the following rule:

"Multiply one-sixth of the lowest tensile strength found stamped on the plates in the cylindrical shell by the thickness—expressed in inches or parts of an inch—and divide by the radius or half diameter, also expressed in inches, and the result will be the pressure allowable per square inch of surface for single riveting, to which add 20 percent where the longitudinal laps of the cylindrical parts of such boiler are double riveted, when all the rivet holes of such boiler, including steam and mud drums, have been fairly drilled

and no part of such holes has been punched. The pressure allowed shall be based on the plate whose tensile strength multiplied by its thickness gives the lowest product."

Using the figures given, your problem works out as follows:

$$1/6 \times 54,000 = 9,000.$$

$$9,000 \times 1.08 = 9,720.$$

$$9,720$$

$$\frac{9,720}{36} = 270 \text{ pounds per square inch, for single riveting.}$$

Add 20 percent to the above result for double riveting and the allowable safe working pressure becomes 324 pounds per square inch.

NEW BOOKS

NAVAL ARCHITECTURE. By W. M. Gray, B.Sc. Size, 5½ inches by 8½ inches. Pages, 201. Diagrams, 100. London, 1923. Methuen and Company, Ltd.

This is a new classbook on naval architecture by the lecturer on naval architecture at the Royal Technical College, Glasgow. The writer has very sensibly confined himself to the science of floating bodies as represented by buoyancy, stability and trim with a chapter on launching and one on riveted joints. Each chapter is followed by questions covering the matter dealt with, and diagrams are freely employed to explain and illustrate the text.

The various subjects have been treated in a clear and simple, as well as a thorough manner, and many students will prefer Mr. Gray's treatment to that in earlier textbooks. New and practical examples of the application of various theories are presented which will serve to stimulate the interest of students without covering too much ground.

The book is excellently printed and bound and is highly recommended for its practical value to all interested in the calculations of ship design.

THEORETICAL NAVAL ARCHITECTURE. By E. L. Atwood, O.B.E. Size, 5 inches by 7¼ inches. Pages, 512. Many diagrams, 6 folding plates. New York, 1923. Longmans, Green and Company.

This is really the eighth edition of the "Text Book of Naval Architecture" first published in 1899 and a standard work of reference in nearly every ship drawing office. But in this latest edition the name has been slightly changed and the scope very considerably increased by the inclusion of chapters dealing with speed calculations, strength, screw propulsion, steering, etc.

The earlier chapters deal concisely with the mathematics of a floating body and have undergone little change in this latest edition, though where there has been a development in theory or method this has not been overlooked, as is evidenced by the treatment of Tchebycheff's rules, Smith's buoyancy correction and the use of the integrator.

There is a chapter also on the Trochoidal Wave Theory which the writer does not remember to have seen dealt with elsewhere outside of Biles' exhaustive "Design and Construction of Ships." In the chapter on Horsepower and Speed there has been made of A. W. John's curves of Residuary Resistance—a very good method but one little used, and for which little data are available. Without space to deal with the form of ships for minimum resistance any method of calculation of power is of little use, and it might have been better if the author had confined himself to explaining the forms of data now in use with their limitations.

The chapter on propellers is also much too short to deal with the matter thoroughly and might well have been omitted from a classbook of this kind.

But any criticism of the work must not detract from a very hearty appreciation of the volume as a whole, and the feeling that for many years to come this book will continue to be one of the indispensables for those who design ships.

The volume concludes with a valuable bibliography in which we notice MARINE ENGINEERING AND SHIPPING AGE finds a place.

PERSONAL MENTION

J. M. WILLIS, general manager of the Baltimore Dry Docks plant of the Bethlehem Shipbuilding Corporation, Ltd., became general manager of the Baltimore Dry Docks Works and Sparrow's Point Works, of the Baltimore plant, Bethlehem Shipbuilding Corporation, Ltd., on March 1, following the consolidation of the shipbuilding and ship repairing interests of the Bethlehem Shipbuilding Corporation, Ltd., in the Baltimore district under one local management with headquarters at Sparrow's Point, Md.

JOHN W. CANTILLION, secretary of the American Bureau of Shipping, completed twenty-five years of service with this institution on February 15, which was also the twenty-fifth anniversary of the date on

J. W. Cantillion

which the battleship *Maine* was blown up in Havana Harbor. Mr. Cantillion joined the American Shipmasters' Association on February 15, 1898. This association was the parent of the present Bureau, the name being changed in November, 1898. At this time the staff consisted of E. Platt Stratton, chief surveyor; J. S. Ritchie, engineer and ship surveyor for steel vessels; Capt. F. A. Martin, consulting surveyor and chairman of the classification committee; Capt. Austin Jayne and Capt. B. F. Cutler, surveyors of wood vessels. While the construction of wooden vessels flourished the Bureau was very active and, when the steel ship construction increased, the staff of surveyors was also amplified. The American Shipmasters' Association, as the American Bureau of Shipping was originally known, was formed in 1862 by the underwriters, shipbuilders and shipowners and these three important branches of the maritime fraternity are still component parts of the organization and are represented in the administration of its affairs. In 1908 this organization, known as the United States Standard Shipbuilders', Shipowners' and Underwriters' Association, was amalgamated with the American Bureau of Shipping. On October 21, 1913, John W. Cantillion was elected secretary of the Bureau, in which office he has continued until the present. In September, 1915, representatives of the shipbuilders, shipowners and underwriters believed that if the Bureau was to be continued it would have to be reorganized. After careful investigation and consideration the committee having induced Stevenson Taylor to become president, the Bureau was reorganized on February 28, 1916, at a meeting of the board of managers. At this meeting Stevenson Taylor was elected president; A. C. Pessano, F. G. Macomber, L. F. Burr and W. H. Todd, vice-presidents, and John W. Cantillion secretary and treasurer. Mr. Cantillion has seen this now efficient organization grow from an infant's size

in wing

with five surveyors to a full man's size organization with branch offices in the principal seaports of the United States and in Tampico, Havana, Rio de Janeiro, Buenos Aires, Balboa, Antwerp, Havre and Hamburg. To the man on the street interested in maritime matters he is known only as John, always endeavoring to aid them in obtaining the facts they desire relative to ships and carrying out the cardinal principles of the Bureau's charter, viz., to disseminate information upon subjects of marine and commercial interest and to aid and develop the American merchant marine.

H. G. SMITH, whose appointment as vice-president of the Bethlehem Shipbuilding Corporation, Ltd., in charge of sales, on January 11 was announced in our last issue, graduated from the United States Naval Academy in 1891 and from the course of naval architecture at the Royal Naval College, Greenwich, England, in 1894. From 1893 to 1903 he served in the Navy as assistant navy constructor and naval constructor, being on duty at the plant of William Cramp and Sons Ship and Engine Building Company, Philadelphia, Pa., from 1894 to 1898 during the building of the *Indiana*, *Massachusetts*, *Brooklyn* and *Iowa*, and also during the period when the American liners *St. Louis* and *St. Paul* were under construction in that yard. From 1898 to 1901 he was on duty at the New York Navy Yard, Brooklyn, N. Y., in charge of ship repairs and the docking of vessels. From April, 1901, until November, 1903, he was on duty in Washington as assistant to the chief constructor of the Navy in charge of designs and current work. Naval Constructor Smith resigned from the Navy on November 1, 1903, and accepted the position of manager of the Fore River Ship and Engine Company, later the Fore River Shipbuilding Corporation and now the Fore River Plant of the Bethlehem Shipbuilding Corporation, Ltd. From 1913 until 1917 Mr. Smith was vice-president and general manager of the Fore River Shipbuilding Corporation and from 1917 until 1920 manager of the Bethlehem Shipbuilding Corporation, Ltd. From 1920 until his present appointment Mr. Smith was assistant to the president of the Bethlehem Shipbuilding Corporation, Ltd.

W. W. SHERLOCK, formerly associated with the Kerr Chartering Company, has now organized a ship brokerage agency with offices in the Maritime Exchange, New York.

A. W. CHRISTIAN has been appointed general sales agent of the Bethlehem Shipbuilding Corporation, Ltd., with offices at 25 Broadway, New York City, to succeed E. B. Germain, resigned.

ALBERT W. HONYWILL, JR. has severed his connections with the Terry Steam Turbine Company, at Hartford, Conn., to take up new duties as assistant to the president of the Diamond Power Specialty Corporation of Detroit.

J. O. PERSONS, SR., formerly New York representative of the Baltimore Dry Dock and Shipbuilding Company and more recently with the Shipping Board, is now representing the Maryland Dry Dock Company, Baltimore, Md., in New York.

CLOYD M. CHAPMAN has become affiliated with Dwight P. Robinson & Company, Incorporated, as consulting materials engineer. Mr. Chapman, who has been active in the work

of the American Society of Testing Materials and the American Concrete Institute, will in the future represent Dwight P. Robinson & Company in the committee work of these societies.

B. H. KNIGHT has been made manager of the Ocean Traffic Bureau of Philadelphia, according to an announcement given out by the president, George F. Sproule.

J. C. JENKINS, director of industrial relations of the United States Shipping Board, has succeeded Capt. Irving L. Evans, who recently resigned, as director of the Sea Service Bureau of the Board. Mr. Jenkins will have full charge of the recruiting service.

PETER J. SHOMER, of The Shomer Company, 510 Kirby Building, Cleveland, O., has been appointed by Row & Davis Engineers, Inc., New York, as their representative in the Great Lakes District. Mr. Shomer was formerly associated with the American Shipbuilding Company, of Cleveland, O.

JOHN HUMBLE, retired shipbuilder, died on February 6 at his home in Buffalo, N. Y. Mr. Humble served an apprenticeship in the Buffalo shipyards, working on some of the first steamships built on the Great Lakes. He founded the firm of Parsons & Humble, shipbuilders, who built the largest wooden hull steamships ever used on the lakes.

A. B. BARBER, of Portland, Oregon, has been appointed manager of the Department of Transportation and Communication of the Chamber of Commerce of the United States, succeeding J. Rowland Bibbins, who has resigned to take up private engineering practice. For the past three years, Mr. Barber served as technical adviser to the Republic of Poland, having been nominated for that work in 1919 by Secretary Hoover, on request of the Polish Government to designate an American engineer to assist in the organization of the railways, coal industry and other technical services. Mr. Barber is a graduate of West Point. Prior to his resignation from the army three years ago to become head of the American technical staff for Poland, he had wide experience with the United States Army Engineers. Soon after the entry of the United States into the war, he was sent to France with a railway commission to report on the needs of the French railways supplying the Allied troops. Later he was assigned to General Pershing's staff, in connection with organization, transportation and overseas shipping. From June to November, 1918, he was at the front with the First Corps, and First and Second Armies. After the armistice, he was assigned to the American Relief Administration, handling the transportation of relief supplies to the various countries of Central Europe. The department, of which Mr. Barber is head, handles the activities of the United States Chamber of Commerce in connection with shipping, ocean and inland; steam and electric railroads, motor transportation; aeronautics and the like.

CAPTAIN IRVING L. EVANS, for several years Director of the Sea Service Bureau of the United States Shipping Board, has resigned that position, according to announcement made by Commissioner T. V. O'Connor, of the Shipping Board. The Sea Service Bureau has been placed under the Division of Industrial Relations, and J. C. Jenkins, Director of Industrial Relations, will have full charge of the Recruiting Service as Director of that division of the Shipping Board.

H. G. Smith

Col. A. B. Barber

The Month's Shipping and Shipbuilding News in Brief

Shipyard, Steamship and Port Activities and Other Notes
of Interest in All Branches of the Marine Industries

North Atlantic Ports Association Started

AT the request of Mr. F. S. Davis, manager of the maritime department of the Boston Chamber of Commerce, a preliminary conference to discuss the advisability of organizing a North Atlantic Ports Association was held in the Commodore Hotel, New York, February 6. Representatives were present from the following organizations:

Directors of the Port of Portland, Maine; Portland Chamber of Commerce, Portland, Me.; Maritime Department of the Boston Chamber of Commerce, Boston, Mass.; Providence Chamber of Commerce, Providence R. I.; New London Chamber of Commerce, New London, Conn. and State of Connecticut; Maritime Association of the Port of New York, New York City; Philadelphia Maritime Exchange, Philadelphia, Pa.; Export & Import Board of Trade, Baltimore, Md.; Baltimore Chamber of Commerce, Baltimore, Md.; Hampton Roads Maritime Exchange, Norfolk and Newport News, Va.

The meeting was called to order by Mr. Davis, who stated briefly the purposes of the conference, viz: "To consider the advisability of forming an organization representative of the North Atlantic Ports as a group, its scope, if formed, and membership, calling attention to the very effective work being done by other similarly constituted port group organizations, such as the South Atlantic Maritime Association and the Mississippi Valley Association, and the West Coast Ports Association." Mr. Davis was elected temporary chairman and Harry M. Thompson, secretary, Hampton Roads Maritime Exchange, temporary secretary.

The chairman called upon each representative for an expression of opinion as regards the purposes of the meeting and all present expressed themselves as being in the main favorably disposed towards forming such an organization which should function along broad general lines, to protect the North Atlantic Group of Ports. In the discussion, however, it developed that there existed some considerable difference of opinion as to the scope of such an organization, if formed, particularly with regard to the propriety of entering into any technical dispute or action.

The following resolutions were adopted:

RESOLUTIONS ADOPTED

Resolved: That it is the sense of this meeting that a North Atlantic Ports Association be formed, subject to the ratification of each organization here represented.

Resolved: "That all commercial organizations of each port on the North Atlantic be eligible to membership in this proposed organization, excluding any such whose obligations and interest extend beyond the port."

Upon motion duly seconded and carried, the present chairman and secretary were continued until a permanent organization effected and their successors duly elected. No action was taken in regard to the appointment of a committee on rules and

Bids Open March 14 for Million and a Half Reconditioning Job on Ward Liners Orizaba and Siboney

BIDS will be received at the office of Theodore E. Ferris, naval architect and marine engineer, New York City, until March 14, for the work of reconditioning the steamships *Orizaba* and *Siboney*, of the New York and Cuba Mail Steamship Company (Ward Line). It is understood that the contract, which provides for the construction of additional deck space and deckhouse extensions, furnishings, etc., will involve a total expenditure of close to \$1,500,000. The vessels are to be back in service next October.

Both ships, which were originally designed as twin screw freight and passenger steamers, have an overall length of 443 feet 3 inches, beam molded 60 feet, depth molded to shelter deck 35 feet, and are of the shelter deck type with decks as follows: boat deck, "A" deck, "B" deck, "C" deck, "D" deck, "E" deck and "F" deck. The propelling plant consists of eight single ended Scotch boilers with two firerooms; twin screws, reduction gear, turbine machinery, oil burning. The vessels were built by the William Cramp and Sons Ship and Engine Building Company.

GENERAL WORK

Both steamers are to be drydocked and undergo special No. 1 survey to Lloyds' Register of Shipping, both port and starboard tail shafts of both vessels are to be drawn for examination, the military mast located between the smokestacks is to be removed, fore and main masts are to be

by-laws, and other committees, pending a full attendance of all organizations not represented at the first meeting, and it was agreed that haste in this phase of the matter was not desirable, but in order to accelerate matters, all present were requested to supply the secretary with a list of the names of such organizations in his port as were considered eligible, which would be consolidated and sent by the secretary to those present, with the call for the next meeting, which it was agreed, upon the invitation of the secretary of the Maritime Association of the Port of New York, would be held in the board room of the New York Maritime Exchange in about a month hence, date being left to the chairman.

Farrell Calls Foreign Traders to Meet in New Orleans

JAMES A. FARRELL, chairman, National Foreign Trade Council, and president, United States Steel Corporation, has called the Foreign Traders of the United States to meet at the Tenth National Foreign Trade Convention in New Orleans, May 2, 3 and 4. The central theme of the convention will be "European Conditions as Relating to World Trade."

lengthened and new rigging fitted, as required. The after end of the boat deck is to be extended at sides and aft; "A" deck closed in, port and starboard, in way of main masts; steel deckhouses built in amidships, port and starboard; the after end of "A" deck, which was formed for depth bomb installation, to be rebuilt, including extension of docking bridge to original condition. There is also to be a new arrangement of derrick posts, booms and winches for handling cargo at the after wing ports to be installed, new canvas decks fitted, sections of new deck fitted, deck covering and tiling to be repaired, and some new to be laid.

The mechanical ventilating and heating system for passenger and crews quarters, as required where not now existing, to be installed, including motors, fans, thermo tanks, etc.; steam heat to be provided in crews' quarters and otherwise as required in accordance with the detailed specifications.

The present electric light wiring throughout the ships is to be removed down to switchboard and the ships rewired new throughout with new electric light fixtures provided, as required. The fresh water system and sanitary system are to be provided for and arranged to suit the new conditions; the communicating system, consisting of telephones and bell calls and a signal apparatus provided, as required.

The present steam windlass and steam hand steering gear are to be overhauled, and the ships are to be cleaned, scaled, painted and finished inside and out, and a sprinkling system provided, as required by the United States Steamboat Inspection Service.

MACHINERY DEPARTMENT

The propelling machinery, boilers, engine room auxiliaries and ice machine, are now and have been operating and no particular amount of work is contemplated in the machinery departments except minor work as covered in the detailed specifications, such as opening of boilers and turbines, grinding of valves, minor repairs and renewals, etc.

"ORIZABA" BOTTOM DAMAGE

In the case of this ship, following an inspection made in drydock by Lloyds' surveyors in August, 1922, after an alleged grounding in New York Bay, it was recommended at that time that permanent repairs to the bottom plating should be carried out, a summary of this damage being as follows: keel plates 9, 10, 11, 12, 16 and 17 indented; "A" strake 9, 10, 11, 12 and 13 indented; "B" strake 8, 9 and 10 indented; "C" strake 6 and 7 indented. It is understood that this particular damage is to be cared for under a separate contract.

PRINCIPAL WORK

Among the principal items mentioned in the specifications are the following:

Deep tanks, Nos. 9, 10, 11, between frames 57 and 65, are to be entirely removed and this space is to be restored to carry cargo with the necessary number of cofferdams. The eight deep wing tanks, Nos. 1, 2, 3, 4, 5, 6, 7 and 8, and double bottom tanks, Nos. 6, 7, 8 and 9 are to be fitted with coils around suction and heater grids in each of these tanks.

All steam and water pipes throughout the cargo and passenger spaces are to be removed and the new piping installed in accordance with detailed plans to be prepared by the contractor and approved by the owner's representative. A large amount of Lit-O-Silo is to be laid on the various decks.

THE "SIBONEY"

A similar amount of general reconditioning work is to be done on the *Siboney*, the principal items of which include the following:

The space between frames 95½ to 101 is to be cleared of berths, lockers, etc., and reconditioned as the crews' hospital, the equipment to include six metal berths. The boat deck is to be extended aft to frame 145 and carried for this length, including that portion from frame 130 to 140 to the sides of the ship.

The sides of "A" deck, from frame 130 to frame 153, are to be decked over to the sides of the ship, of the same construction as the present deck. To support this extension a steel girder is to run the full length of this portion of the deck, fastened to beams and supported by a steel tubular column resting on "C" deck, this column to be of sufficient strength to support the deck and four small booms for handling cargo, each about 17 feet long and about 3 tons' capacity.

On "A" deck the space between frames 44 to 62 is to be reconditioned and arranged for six passenger staterooms de luxe with adjoining bathrooms. While the space between frames 69 and 91, occupied at present by temporary staterooms, is to be cleared and reconditioned to form reading room, writing room and lounge.

On "A" deck, between frames 90 to 111, both sides, a new deckhouse extension is to be built each side of the main house, each of these houses to be fitted up with passenger staterooms, shower bath, etc.

On "B" deck the space between frames 42 and 52 is to be reconditioned to form suite, bedroom and bath, while that between frames 52 and 55 is to be reconditioned by installing new berths and fittings.

In addition to considerable other reconditioning work for the providing of passenger accommodations, the contract will call for the overhauling of the various mechanisms on both ships, the replacement of various systems, motors, galley equipment, etc.

Bids Asked for Construction of Semi-Diesel Electric Towboat

SEALED proposals will be received by U. S. Engineer Office, Nashville, Tenn., until 11 A. M., March 6, for the construction and delivery of one 80-foot semi-Diesel electric towboat. The vessel is to be delivered at Nashville, Tenn., and is to have a length overall of 98 feet 4 inches, length molded 80 feet, breadth molded 20 feet, depth molded 4 feet 6 inches.

MACHINERY

The main engine will be a multiple cylinder, 2-stroke cycle, heavy duty, semi-Diesel oil engine and is to be of American manufacture.

Agamemnon and Mount Vernon Committee Submits Recommendations

THAT extensive reconditioning contracts on the steamships *Agamemnon* and *Mount Vernon* are drawing materially nearer is indicated in latest information obtained by MARINE ENGINEERING AND SHIPPING AGE. It was announced in these columns on December 9, 1922, that a committee of prominent shipping men had made an investigation of the ships and preliminary estimates of the reconditioning cost were given out.

It was recently learned that the committee's report has been completed and forwarded to Washington and while no official statement could be obtained it is believed that these two great ships will be converted either into passenger ships or as seaplane carriers.

Reconditioning of the *Agamemnon* and the *Mount Vernon* as passenger ships would probably reach a total cost of close to \$5,000,000. No estimates could be obtained on their conversion as aeroplane carriers.

Bids for Reconditioning of America Due Early in March

ACCORDING to the latest information available, it is believed that plans and specifications for the reconditioning of the steamship *America* will be issued from the Shipping Board, 45 Broadway, New York, about March 2, bids to be received a week later. The contract will involve the expenditure of close to half a million dollars. It is understood that the ship will be placed in drydock in New York for necessary bottom work so that in the event of the contract being placed in another city the ship will proceed direct from New York Harbor.

The *America* has an overall length of 687 feet and it is expected that after her conversion she will be the largest cabin carrier in the world. Specifications will cover reconditioning of the hull and machinery, the rearrangement of present and installation of additional public rooms; overhauling the present, and wherever necessary, the installation of new systems such as ventilating, heating, electric, sanitary, etc.

New York and Porto Rico Line Ship Specifications Issued

PLANS and specifications for the construction of a passenger and cargo ship for the New York & Porto Rico Line have been issued from the office of Theodore E. Ferris, naval architect, 30 Church street. Bids will be received at that office until 12 o'clock noon, March 20, and it is believed the cost will be in excess of a million and a half dollars.

The proposed ship will have an overall length of 428 feet 3 inches; length between perpendiculars, 412 feet; beam, molded, 57 feet 6 inches; depth to hurricane deck at side, 36 feet 6 inches; designed load draft, 23 feet 6 inches; deadweight capacity at load draft, 4,250 long tons; speed at load draft, 15½ knots.

TYPE OF SHIP

The vessel will be of the three-deck, hurricane deck, coastwise type with fore-castle, deck well, bridge enclosure and continuous deck erections aft; complete double bottoms; lower, main, hurricane, promenade and boat decks, and two steel pole masts.

PROPULSION

The propelling machinery will consist of a Parsons design turbine engine, with reduction gears turning a single screw. At 87 revolutions per minute, the shaft horsepower will be about 5,800. Steam will be supplied by five Scotch boilers, equipped to burn oil for fuel.

EQUIPMENT

The steamer's accommodations will be sufficient for 305 first class passengers and 82 second class.

A separate price will be submitted by bidders for the installation of an air cooling

refrigerating and insulation system capable of cooling practically all of the ship's cargo space for the carrying of citrus fruits.

Annual Motor Boat Show Opened in New York

THE annual National Motor Boat Show, which is being held at the Grand Central Palace, New York, from February 21 to March 3, gives yachtsmen an opportunity to inspect a complete display of power driven craft, ranging from an eight-foot Kiddie Canoe to a sixty-foot ocean cruiser.

Several important meetings are scheduled in New York during the period of the show, including those of the United States Power Squadrons, the Waterway League of America, the American Power Boat Association, the Society of Automotive Engineers, the National Association of Engine and Boat Manufacturers, the International Power Boat Union and the Mississippi Valley Power Boat Association.

The show is held under the auspices of the National Association of Engine and Boat Manufacturers.

University of California Offers Instruction on Ships and Shipping

THE University of California Extension Division has organized class instruction in San Francisco, on ships and shipping. Charles F. Gross, assistant professor of marine engineering and naval architecture at the University, is the instructor of the first course along this line which has been attempted. Many prominent men in shipping circles have enrolled and the class recently organized already totals nearly 100.

The first course is an elementary one, and consists of ten 1½-hour lectures on such subjects as types and classification of merchant vessels, relations between different tonnages, stability, manning requirements, wages and duties of crews. The instruction will also include a brief description of marine power plants.

Plans are now being laid for more advanced courses on the completion of the present one covering ships and shipping.

British Naval Architects to Hold Annual Meeting March 21-23

THE annual meeting of the Institute of Naval Architects will be held on March 21, 22 and 23, in the Lecture Hall of the Royal United Service Institution, Whitehall, London, W. C. 2, with His Grace the Duke of Northumberland, C.B.E., M.V.O., president, in the chair. The annual dinner will be held on March 21 at 7:30 P. M. in the Grand Hall, Connaught Rooms, Great Queen street, Kingsway, London, W. C.

Electric Contract for Diesel Barges Goes to G. E. Co.

THE General Electric Company has been awarded a contract for the electric equipment to be used on the two Diesel-electric, self-propelled barges, which have been ordered by the Minnesota All-Water Transit Company, of Duluth, from the Great Lakes Engineering Works. The equipment of each barge will consist of two Lombard-Governor Diesel engines, directly connected to a 250-kilowatt, direct current generator, which in turn will supply electricity to drive two 250 horsepower motors, one attached to each of the twin screws. The motors are rated at 180 revolutions per minute, which will give the barges a speed of approximately eight knots.

The vessel will be controlled from the pilot house. They were designed by Henry Penon, of Cleveland, and will have a length of 254 feet and beam of 42 feet.

Navy Department in Need of Draftsmen for Small Boat Work

The United States Civil Service Commission announces an open competitive examination for ship draftsmen, Grade A (small boats). Vacancies in the Bureau of Construction and Repair, Navy Department, Washington, D. C., at \$6.80 to \$8.80 per month (plus bonus), and vacancies in positions requiring similar qualifications, at these or higher or lower salaries, will be filled from this examination, unless it is found in the interest of the service to fill any vacancy by reinstatement, transfer, or promotion.

Appointees at annual compensation of \$2,000 or less, whose services are satisfactory, may be allowed the increase of \$20 a month granted by Congress.

Marine Examinations

The United States Civil Service Commission announces an open competitive examination for junior engineer and deck officer. Vacancies in the United States Coast and Geodetic Survey, at the entrance salary of

\$2,000 a year, and in positions requiring similar qualifications, at this or higher or lower salaries, will be filled from this examination, unless it is found in the interest of the service to fill any vacancy by reinstatement, transfer, or promotion. Applications will be rated as received until June 30, 1923. Successful applicants will be notified.

Over Two and One-Half Million Dollars' Worth of Port Improvements Contemplated by New Orleans, La.

OVER two and one-half million dollars is expected to be spent for port improvement enterprises at New Orleans, La., in the near future, according to information obtained by MARINE ENGINEERING AND SHIPPING AGE. Pier work, freight sheds, dredging, etc., are among the projects under consideration.

Among other things, plans and specifications, which are waiting approval, provide for the construction of new wharves, sheds, etc., at the foot of Claiborne Street, at a cost estimated at \$1,800,000; for the renewing of about 400 lineal feet of wharves with steel structure freight sheds at the foot of Poland Street, to cost approximately \$275,000; and for the reconditioning and extension of sheds at the foot of Celeste

Street, which will cost close to \$200,000, and the foot of St. Joseph and St. Andrews Streets, at approximately the same cost for each location. Plans and specifications have also been prepared for enlarging of sheds and improvement of the sewerage and drainage systems at the foot of Canal Street.

These projects are under the jurisdiction of the Board of Port Commissioners who will receive sealed proposals at their office, Suite 200, New Court Building, until 3 P. M., February 1, for furnishing 50,000 cubic yards of sand, delivered at the Industrial Canal site, New Orleans, La.

The same office will open at 3 P. M., on February 1, tenders for furnishing and renewing woodwork for the 7th Street shed.

Bids Received on February 24 for Construction of Two Barges and a Steel Quarter Boat

BIDS were opened at 11 A. M., February 24, by United States Engineer Office, Wilmington, Del., for the construction and delivery of one steel quarter boat and two steel barges.

The quarter boat is to have a length of 80 feet, beam molded 26 feet, depth molded 5 feet, and is to be a 34-man vessel. The equipment for the vessel is to include a steam engine generating set, generator rated at three kilowatts, 110 volts, 700 revolutions per minute; fresh water pressure system, sanitary system, hot water pressure system and complete sets of plumbing fixtures of

heavy type Sands, Standard, Mott, or equal. A fire and bilge pump, 4½ inches by 5 inches by 6 inches, Davidson Simplex, or equal; and a sanitary pump, 5¼ inches by 5 inches by 6 inches, Worthington, or equal, are also to be installed.

The steel barges are to have a molded length of 60 feet, beam molded 22 feet, depth molded 4 feet. Each barge is to have two transverse watertight bulkheads and is to be fitted with four 7-inch cast iron bitts of approved design.

The quarter boat and barges are to be delivered afloat, at A and Poplar Streets, Wilmington, Del.

America's Foremost Shipping Men Address Propeller Club of the Port of New York at Noon-Day Luncheon

WHAT the Shipping Board is doing for the promotion of a successful American Merchant Marine was the theme of an address by Joseph E. Sheedy, vice-president of the Emergency Fleet Corporation, at a meeting of the Propeller Club of the Port of New York, on February 23. The results of the Board's policies, Mr. Sheedy stated, will be advantageous to American shipping, irrespective of the fate of the subsidy bill.

Commenting on the \$138,000,000 budget for the Board this year, Mr. Sheedy said that the principal items of expense for ship operation are as follows: fuel, 28 percent; stevedore and cargo handling, 23 percent; port charges, 10 percent; repairs, 12 percent and wages, 12 percent.

Other speakers included Stevenson Tay-

lor, president of the American Bureau of Shipping; R. D. Gatewood, director of the Division of Maintenance and Repairs, of the Shipping Board; Captain W. E. Griffith, operating manager; and Captain C. A. McAllister, vice-president of the American Bureau of Shipping.

All of the speakers spoke in high praise of the Propeller Club, the object of which is promotion of the "get-together" spirit, through informal luncheon meetings held twice a month. Its officers are:

W. Z. Gardner, president; J. Bonner, vice-president; H. W. Parsons, treasurer; B. L. Todd, secretary; Norris R. Sibley, of the London Steam Turbine Company, chairman membership committee; S. L. Lemon, of the W. A. Harriman Company, chairman executive committee.

Two Ferryboats Contemplated

THE Westchester Ferry Company, represented by the Mercury Shipping Company of 17 Battery Place, New York City, through Leo E. Schwarstein, is taking up with various shipyards the question of the construction of two ferryboats to run across the Hudson river in the vicinity of Yonkers.

Shipyard Expansion

The George T. Johnson & Sons' construction and repair yard, Cambridge, Md., is expanding its facilities through the installation of a new marine railway and various new machinery, having recently completed other improvements. The plant constructs yachts, lighters, barges and tugs and is at present building a twin screw houseboat for Charles V. Bossert, of Brooklyn, N. Y.

International Conference

The subject of "National Restrictions on Maritime Transportation" will be one of the topics discussed by group sessions at the second general meeting of the International Chamber of Commerce to be held in Rome, Italy, March 18 to 24. A. C. Bedford is chairman of the American committee and the American delegation headquarters will be at the Grand Hotel, Rome.

Marine Construction News of the Month

Ship Contracts—New Ship Concerns and Shipyard Improvements—Terminal Projects—Government Contracts

SHIPS AND SHIPBUILDING

Barge Repairs, Philadelphia, Pa.—The damaged barge Theodore H. Rodhe was towed to Philadelphia for repairs.

Steamer Drydocked, Portland, Ore.—Steamer West Kents was awarded the Helser Iron Works for collision damage repairs.

Storm Damage Job, Winslow, Wash.—The storm-battered barkentine James Tuft was taken to Winslow, Bainbridge Island, for repairs.

Ship Drydocked, Mobile, Ala.—The tanker Mary Luckenbach has been placed on the dock at the Todd plant, Mobile, for overhauling.

Extensive Repairs, Baltimore, Md.—The H. E. Crook Company received the contract for extensive repairs to the Old Bay liner Alabama.

Repairs to Plates, Cleveland, O.—Steamer Quincy A. Shaw has been placed on No. 1 drydock, Cleveland, to have nineteen damaged plates repaired.

Steamer Reconditioned, Algiers, La.—The Shipping Board steamer West Hardaway has been placed on drydock at Algiers to be reconditioned.

Tanker Repairs, Mobile, Ala.—The Danish tanker Gedania has been placed on the drydock of the Alabama Dry Docks plant for considerable repair work.

Steamer Drydocked, Buffalo, N. Y.—Steamer Harvey D. Goulder was drydocked at Buffalo to have seventeen plates removed and thirteen faired in place.

Drydocking and Hull Cleaning, San Francisco, Cal.—The dreadnaught Arizona was taken to San Francisco to be drydocked and to have her hull cleaned.

Extensive Overhauling, Seattle, Wash.—The steamship Victoria, of the Alaska Steamship Company, has undergone an extensive overhauling and remodeling.

Engine Repairs, Chester, Pa.—The Squ Shipbuilding Company has been awarded repairs to main engine on the Vacuum Oil Company's motorship Brammell Point.

Reconditioning, Brooklyn, N. Y.—Steamer American Legion, of the Munson Line, was awarded to the Atlantic Basin yard, to be reconditioned at a cost of \$8,894.

Barge Overhauled, Galveston, Tex.—The whale-back barge Freeport Sulphur No. 4 was awarded to the Galveston Dry Dock & Construction Company to undergo an overhauling.

Motorboat Conversion, New Orleans, La.—The Johnson Dry Dock and Ship Repair plant has been awarded the contract to convert the gasoline motorboat Paul to a steamboat.

Tanker Contract, East Oakland, Cal.—The Hanlon Shipbuilding and Dry Dock Company was awarded repairs on the tanker Tutsum of the United States Shipping Board, at a price of \$688.20.

Contract Awarded, Galveston, Tex.—The Galveston Dry Dock & Construction Company was awarded the contract for repairs to the damaged steamer Schoodic, at a price of \$27,450.

Additional Vessels.—The Robert Dollar Company has purchased the British steamship Wayfarer, 15,000 deadweight tons, and the steamship Warszawa from the Polish Navigation Corporation.

Contract Awarded, Brooklyn, N. Y.—The contract for repairing the tanker H. M. Flagler, of the Standard Oil Company, was awarded the Morse Dry Dock & Repair Company, on a bid of \$11,841.

Tug Launched, Brooklyn, N. Y.—The first of three steel tugboats building for the New York

Central Railroad, Tug No. 30, was launched from the Tebo plant of the Todd Shipyards Corporation.

Yacht Reconditioning, New Bedford, Mass.—The seagoing yacht Harpoon, owned by Nathaniel O. Goode, is to be fitted with two high-powered inclined engines, Fayette type. Cost about \$100,000.

Low Bidders, Oakland, Cal.—The Moore Drydock Company was low bidder on a big general overhauling job on the engines and boilers of the Pacific Mail liner President Taft, with a price of \$18,865.

Repairs and Painting, Baltimore, Md.—The Baltimore Dry Dock Company has completed painting and repairs on the steamer Santa Rosa and has started work on the Shipping Board steamer Capulin.

Overhauling of Vessel, San Francisco, Cal.—The Bethlehem Shipbuilding Corporation was awarded the work of overhauling the Admiral Line steamer Senator, the work including refitting and changing of staterooms.

Cleaning and Painting, Portland, Ore.—The contract for repairs to the propeller and cleaning and painting the hull of the steamship Kentuckian has been awarded the Helser Iron Works, Portland, at a price of \$5,000.

Barkentine Damaged.—The five-masted barkentine Molfetta, which hit on a sand spit while sailing up the mouth of Pensacola harbor, Fla., was found to have been damaged, and has been dry-docked in Pensacola for repairs.

Oil Barge Construction, San Pedro, Cal.—The Associated Oil Company has awarded the contract for the construction of a steel oil barge to the Los Angeles Shipbuilding and Drydock Corporation, to cost approximately \$45,000.

Vessel Remodeling, Sparrows Point, Md.—Steamer Mary Weems, of the Baltimore & Carolina Steamship Company, will be reconditioned and remodeled at the Sparrows' Point plant of the Bethlehem Shipbuilding Corporation.

Tanker Launched, Chester, Pa.—The American tanker Pennsylvania Sun, built for the Sun Oil Company by the Sun Shipbuilding Company, Chester, has been launched. The ship is 480 feet long with a beam of sixty-five feet.

Barge Construction, Los Angeles, Cal.—The Los Angeles Shipbuilding & Drydock Corporation has been awarded the contract for the construction of a steel oil barge for the Associated Oil Company. Approximate cost, \$35,000.

Contract Awarded, East Oakland, Cal.—The Hanlon Shipbuilding and Drydock Company was awarded the steamer Stanley Dollar, recently purchased from the Robert Dollar Steamship Company by R. Chamberlain, for reconditioning.

Repairs to Steamer, Oakland, Cal.—The White Flyer Line steamer Humboldt was placed on the Moore drydock to undergo extensive reconditioning, work including rebuilding of hull and superstructure and installation of a new deck aft.

Repairs to Steamers, Baltimore, Md.—The Shipping Board awarded electric work on the steamer Winston-Salem to Mason & Roe at \$950, boiler work to the Pioneer Service Corporation at \$1,020, and machinery repairs to Theodore H. Rhode, Inc., at \$3,843.

Tug Launched, Brooklyn, N. Y.—New York Central Tug No. 31 was launched at the Tebo plant of the Todd Shipyards Corporation, this vessel being the second of three steel tugs constructed by the Todd Corporation. All are equipped with Todd oil burners.

Engines Supplied, Auburn, N. Y.—McIntosh and Seymour, of Auburn, N. Y., have been awarded the contract to supply the twin internal combustion engines of 600 horsepower, reversible Diesel type, for the Canadian Pacific ferry, to ply between Bellin-

ham and Vancouver Island, which is now being built by Yarrows of Esquimalt.

Overhauling of Steamship, New Orleans, La.—The steamship San Ramon, recently sold to the Donovan Lumber Company, of Aberdeen, Wash., by the New Orleans Coal and Bisso Towboat Company, has been overhauled and put in condition by her former owners.

Seagoing Vessels Contracted For, United States.—There were thirty-one seagoing steel vessels, having a total gross tonnage of 165,695, building and contracted for in the United States on January 1, 1923, according to statistics compiled by the American Bureau of Shipping.

Rivet Replacements, Oakland, Cal.—The Moore Drydock Company received the contract for making repairs to the damaged steamer Celtic Prince, which consisted largely of replacement of damaged rivets, the work being done by aid of divers 25 feet beneath the surface of the bay.

Radio Contracts, West Coast.—The Alaska Packers' Association is reported as having contracted with the Radio Corporation for the installation of radio sets on the ships Star of Russia, Star of Italy, Star of France, Arapahoe, the barks Edward Sewell, Star of Scotland, and the steamer Chilkat.

Chain Contract Award, Cleveland, O.—The National Malleable Castings Company has been awarded a contract for equipping five new 600-foot freighters now under construction at the Lorain Yard of the American Shipbuilding Company. Each boat will be equipped with two 90-fathom lengths of 2¼-inch Naco chain.

Miscellaneous Repairs, Mobile, Ala.—Steamship Bethlehem was placed on the dock of the Alabama Dry Dock & Shipbuilding Company for scraping and painting, after which she was moored at the Pinto north wharf of the plant where repairs to her steam lines, electrical system, fuel oil pumps and boiler room were completed.

Ferry Contracts, West Coast.—The contract for building two ferries for the Long-Bell Lumber Company has been awarded the St. Helens Shipbuilding Company. These ferries will operate between Longview, on the Washington side of the Columbia, and Ranier, Ore. The boats will be equipped with Diesel engines and will have a length of 120 feet.

Steamer Overhauled, Sparrows Point, Md.—The steamship Columbia, being overhauled by the Bethlehem Shipbuilding Corporation, at Sparrows Point, will be renamed the City of Atlanta, when she leaves the plant. The work included overhauling of engines and boilers, installation of a number of staterooms and bathrooms, and the whole re-decorated.

Steamer Launched, Lorain, O.—Steamer Joshua A. Hatfield, building for the Pittsburg Steamship Company, has been launched at the Lorain yard of the American Shipbuilding Company. The vessel is 600 feet over all, 580 feet keel, 60 feet beam, 32 feet deep. The steamer will have a triple expansion, reciprocating engine with cylinders 24½ by 41 by 65 inches, with 42-inch stroke.

Shipyard Activities, West Coast.—The Hanlon shipyards have delivered the army quartermaster's department water barge El Aguador, after installing a new wheel and drawing her tail shaft, as well as other repairs. The Standard Oil tanker Tachee was placed on Hunter's Point drydock to undergo the placing of a new rudder stock and to have her tail shaft drawn. The Pacific Mail liner Ecuador has been placed on the Bethlehem ways to have several of her bottom plates renewed.

Contracts Awarded, Mobile, Ala.—The Alabama Dry Dock & Shipbuilding Company has received the following contracts: steamer Hancock County, to be fitted out for passenger accommodations and for repairing and refinishing of captain's and chief officers' rooms; Mexican steamship Santa Alicia, plate

work, bridge work, machinery jobs and repairs to entire wood deck; junior mine planter Major Albert G. Jenkins, cleaning, painting and minor repairs; and tug John W. McKie, installation of rudder and propeller, and miscellaneous repairs.

Contracts Awarded, Mobile, Ala.—The Alabama Dry Dock & Shipbuilding Company, of Mobile, Ala., was awarded the following contracts: installing of new tail shaft and wheel to steamship Yumuri, of the Ward Line; repairs to the Saugerties, of the Tampa Intercoastal Steamship Company; drydocking for inspection and repairs to the steamship Dirigo, of the Texas Company; fitting out cabins for additional passengers and other minor repairs to the steamship Lake Fairport and bottom calking, scraping and painting to the four-masted schooner Alpena.

Conversion, Brooklyn, N. Y.—With the conversion of the steamships Santa Marta and Zacapa, now at the plant of the Robins Dry Dock & Repair Company, the United Fruit Company will complete its program of converting all steamships, operating out of the Northern Division, from coal to fuel oil burners. The United Fruit Company's fleet, equipped for burning oil by the Todd Shipyards Corporation, includes the following vessels: Tolosa, Calamares, Pastores, Tivives, Carrillo, Metapan, Santa Marta, Zacapa, San Jose, San Mateo, Limon and Esparta.

Contract Awarded, Sparrows Point, Md.—The Bethlehem Shipbuilding Corporation, Sparrows Point, received the contract for the construction of two passenger steamers for the Eastern Steamship Lines, Inc., of Boston, Mass. Approximate total cost, \$3,800,000. Deliveries provided for April and May, 1924. Each vessel will have length overall of 402 feet, length between perpendiculars 385 feet, beam over guards 72 feet 6 inches, load draft 16 feet 6 inches. They will be twin screw, turbine driven, all burning, have a nominal speed of 17 knots and 6,310 tons displacement; night boats for service between New York and Boston, operating through the Cape Cod Canal.

PORT IMPROVEMENTS

Navigation, Etc., Orange, Tex.—\$750,000 has been voted by Orange County, Tex., for navigation improvements on Sabine River.

Ferry Docks, Windsor, Ont.—New docks are planned at Windsor by the Detroit Windsor Ferry company at a cost of \$500,000.

Electric Crane, Ogdensburg, N. Y.—The Hall Coal company is planning to replace the electric crane destroyed by storm last season. Price \$40,000.

Harbor Improvements, Houston, Tex.—Harris company and the City of Houston have voted \$4,000,000 bonds for harbor and dock improvements. C. McVea, city engineer.

Grain Elevator, Etc., Goderich, Ont.—Goderich Elevator & Transit Company, Horton street, London, is having plans prepared for a grain elevator, \$50,000, and also improving harbor \$250,000.

Grain Elevator, Burrard Inlet, B. C.—A grain elevator on 150 by 1,650 foot site, at Burrard Inlet, being planned by E. A. Woodward Grain Company, Ltd., 721 Grain Exchange, Winnipeg, Manitoba. Price \$500,000.

Grain Elevator, Duluth, Minn.—Occident Elevator company, Board of Trade Building, plans a 6-story, 0 by 250 foot grain elevator of reinforced concrete, on pile and concrete foundation, at Rices Point, to cost \$900,000.

Contemplated Improvements, New Orleans, La.—Over two and one-half million dollars is expected to be spent for port improvement enterprises at New Orleans, La., in the near future. Pier work, eight sheds, dredging, etc., are among the projects under consideration.

Grain Elevator, Ft. William, Ont.—James Stewart Grain Company had plans prepared for a 1,500,000 bushel terminal grain elevator, concrete, \$850,000. The pile foundation was awarded to the Thunder Bay Harbor Improvement Company, Molsons Bank Building, Port Arthur, at \$150,000.

Pier, San Diego, Cal.—The United Dredging Company, foot of Beech street, was awarded the contract for 305,000 cubic yards of dredging at \$0.295 per cubic yard, 12,000 ton rock fill at \$2.70, constructing curtain walls, etc., at \$87,525, by the Common Council constructing first unit of mole type No. 2.

Excavation, Fort Pierce, Fla.—Excavation in the North St. Lucie river drainage district, during the month of December, totaled 206,772 yards, according to the monthly report of operations. This brings the total excavation up to nearly four million yards, or about two-thirds of the total project, which it is estimated will be completed in another year. The monthly excavation in the district is again approaching normal, after several months of hindrance on account of high water.

Drainage Projects, Tallahassee, Fla.—Five new drainage projects, contemplated by the Everglades drainage board for the coming year, have been approved, it was announced by F. C. Elliott, chief engineer of the board, upon his recent return to the capital from South Florida. They include construction of an intercepting canal, at a point fourteen miles south of Lake Okechobee, east of Hillsboro and North New River canals; and construction of levees on the West Palm Beach and Miami and South New River canals.

GOVERNMENT WORK

Dredging, New York, N. Y.—U. S. Engineer, 1st District, plans dredging at Flushing Bay.

Dredging, New York, N. Y.—U. S. Engineer, 2nd District, plans to dredge in Shrewsbury River.

Waterway Dredging, Galveston, Tex.—U. S. Engineer, Galveston, plans dredging Sabine-Neches Waterway.

Dredging, Providence, R. I.—U. S. Engineer, Providence, plans maintenance dredging in Connecticut River.

Harbor Improvement, New Orleans, La.—U. S. Engineer, 329 Custom House, plans to dredge Intercoastal Waterway, near Houma.

Derrick Boats, Etc., Nashville, Tenn.—U. S. Engineer is planning to purchase 2 steel derrick boats and 9 barges for revetment work.

Maneuver Boat, Savannah, Ga.—U. S. Engineer Office, plans to purchase a maneuver boat for Dam 30, Ohio River, also plans repairs to dredge Macon.

Dredging, San Diego, Cal.—United Dredging Company, Exposition Park, Los Angeles, received the contract for dredging in San Diego Harbor. Price \$103,876.

Rip-rapping Diike, Mare Island, Cal.—Specification 4775—Bureau of Yards & Docks, Navy Department, Washington, D. C., is planning rip-rapping dike, Mare Island.

Pier, Etc., Boston, Mass.—Specification 4778—Bureau of Yards & Docks, Navy Department, Washington, D. C., plans fuel oil pier, bulkhead and dredging, at Boston.

Reconstructing Dikes, Mare Island, Cal.—Specification 4776—Bureau of Yards & Docks, Navy Department, Washington, D. C., plans reconstructing dikes 9 and 14, Mare Island.

Barges, Milwaukee, Wis.—U. S. Engineer, Federal Building, awarded contract for five barges and installation of machinery in same, to Greenbay Dry Dock Company, Greenbay, Wis., at \$72,400.

Crane, Washington, D. C.—The Chief of Engineers Office, 250 Old Land Office Building, has awarded the contract for one steam locomotive crane to McMyler-Interstate Company, Bedford, O. Price \$5,870.

Lock Gates, Pittsburgh, Pa.—John Eichleay, Jr., Co., 45 South Twentieth street, was awarded the contract by the U. S. Engineer, Pittsburgh, for steel lock gates for Lock 1, Allegheny River, at a price of \$7,371.

Excavating, Wilmington, Del.—The Delaware Dredging Company, 139 South Third street, Philadelphia, Pa., was awarded the work of excavating cut-offs in St. Jones and Mispillion Rivers, by U. S. Engineer. Price \$45,632.

Contract Awarded, Buffalo, N. Y.—The American Construction Company, Marion Building, Cleveland, Ohio, was awarded the contract for constructing a stone and concrete superstructure on breakwater in Buffalo Harbor, at a price of \$447,609.

Pier Extension, Puget Sound, Wash.—Specification 4707—Bureau of Yards and Docks, Navy Department, Washington, D. C., awarded a contract to Henry & McFee, 208 Northern Life Building, Seattle, for extension to pier, Puget Sound, at a price of \$395,173.

NEW INCORPORATIONS

Great Central Forward Company, of New York, capital \$12,000, chartered under Delaware laws.

The New York Port Terminal Company, capital \$1,000,000, to build docks, chartered under Delaware laws.

Fort Myers Steamship Company, Fort Myers, Fla., capital \$100,000. President, I. W. Riggs; secretary and treasurer, Harry Botts.

The Canadian-American Bureau of Trade, of Manhattan, shipping agents, capital \$20,000, chartered at Albany. Incorporators: E. B. Beacham, D. W. Harris and T. R. Fleming.

Polarus Shipping Company, ship brokers, capital \$125,000, incorporated under Delaware laws. Incorporators: Captain T. N. Agapeyeff, Marcel Levy and Charles Dunaif, of New York.

Porto Rican American Steamship Corporation, capital \$2,000,000, to do business in coal and timber, chartered in Delaware. Incorporators: Wm. H. Stayton, Sr., Wm. H. Stayton, Jr., and Arthur J. J. Townsend, of Baltimore.

FOREIGN ACTIVITIES

Shipyards Reopened, Ireland.—After having been closed for some months, the yard of the North of Ireland Shipbuilding Company, Ltd., Londonderry, has been reopened.

Contract Placed, Belfast, Ireland.—An order has been placed with Workman, Clark & Company, Ltd., Belfast, for the construction of a large passenger and cargo steamer for the Eastern trade.

New Vessel, Scotland.—The Ailsa Shipbuilding Company, Ltd., Troon, has received an order from Messrs. William Sloan & Company for the construction of two steamers, each of about 1,130 tons gross, similar to the Findhorn and the Annan, built at Troon for the same owners in 1903 and 1907, respectively.

Tonnage Output, British Company.—The Shipyards of Swan, Hunter & Wigham Richardson, Ltd., show a tonnage output during 1922 of 119,652 tons. This figure includes only ships launched on the Tyne and at yards on the Wear, on the Clyde and in Ireland, exclusively owned by the firm, and is the largest output of any British shipbuilding company.

New Steamer, Italy.—The steamer Laura, built at Cantiere Navale Triestina di Navigazione, has been successfully launched. She has a gross tonnage of 6,131; net tonnage of 3,718; length of 127.44 meters; breadth, 16.47 meters; draught, 10 meters. The vessel has engines of 2,200 horsepower, which will give a speed of 10½ nautical miles per hour.

Spanish Steamer Trials.—Having passed successful trials, the light cruiser Reina Victoria Eugenia, built at Ferrol Dockyard, has been handed over to the Spanish Government. She displaces 5,590 tons, is 462 feet long overall, 50 feet beam, 15 feet 9 inches mean draft, and has a speed of 26 knots. She has twelve Yarrow type coal-fired boilers, and her Parsons turbines develop 25,500 shaft horsepower, on two shafts.

Vessel Construction for Sweden.—According to announcement by the Swedish-American Steamship Line, which operates a fleet of passenger and freight vessels between New York and Gothenburg, an order is to be placed in a British yard for a new 16,000 gross ton liner. The ship will be 580 feet long with a 70-foot beam, and will accommodate 100 first, 400 second, and 1,000 third-class passengers. Delivery, 1924.

Contracts Placed, Rotterdam, Holland.—C. Van Der Giessen & Zonen's Scheepswerven, of Rotterdam, have received the following contracts. One motor vessel for river trade, to carry passengers and cattle, for Dutch owners, having a Bolnes 4-cylinder motor of 260 horsepower, the boat being 148 feet by 23 feet by 8 feet; and a shelter deck cargo steamer of 6,600 tons deadweight, for Dutch owners, having triple expansion engines furnished by Rotterdam Drydock Company, the vessel being 360 feet 6 inches by 50 feet by 32 feet 6 inches.

Progress Being Made on \$3,000,000 Port Development

NORFOLK, Va., January 25.—Work on the new \$3,000,000 coal pier of the Virginia railway, for which contracts were awarded two months ago on which construction was immediately started, has made substantial progress.

Sanford & Brooks have been engaged in piling for the pier and in building a bulkhead since the week after the contracts were let. The bulkhead is now about three-fourths finished.

TRADE PUBLICATIONS

AIR FILTERS.—A new edition of the Midwest Steel and Supply Company (New York) catalog, covering the apparatus made by this company for handling dirt and dust problems, and air filtration for industrial plants, will be distributed within a short time.

BOILER CAPACITY.—A folder outlining three features of Heine boilers—economy, flexibility and capacity—has been distributed by the Heine Boiler Company, St. Louis, Mo. An installation of oil-fired Heine boilers, in which these features accomplish excellent results in cutting down cost, is given as a notable example.

INDUSTRIAL LIGHTING.—A new series of six bulletins on systems of lighting for various industrial uses has been issued by the Edison Lamp Works of the General Electric Company, Harrison, N. J. These bulletins cover the lighting of textile mills, pulp mills, woodworking plants, street lighting and the like. Former issues of lighting bulletins have been revised and brought up to date and may be obtained upon request.

CONICAL MILLS.—Conical ball and pebble mills and their application to the field of grinding and pulverizing are described in catalog No. 13 issued by the Hardinge Company, New York. The various methods of grinding for metallurgical purposes, the manufacture of cement, and in the fuel field are taken up in detail with an illustrated description of the construction of Hardinge mills and their applications. Specifications and applications of these mills are included in the bulletin.

SEAMLESS BOILER TUBES.—The manufacture, properties and uses of "Shelby" seamless hot rolled boiler tubes are detailed in Bulletin No. 12 of the National Tube Company, Pittsburgh, Pa. One of the most important uses for seamless steel tubing is in boilers and until late years cold drawn tubes were found more satisfactory than those made by other processes. However, the process of hot rolling has been so far developed that tubes made by this process are becoming more generally used. Tables of properties of "Shelby" tubes and other useful data are contained in the Bulletin.

PUMPS AND GEARS.—The Waterbury hydraulic variable speed gear, as applied to ship's deck auxiliaries and the Waterbury variable delivery pump used for ship's steering gears are illustrated and described in bulletins sent out by the Waterbury Tube Company, Waterbury, Conn. In driving winches, capstans, windlasses and other deck machinery where electricity is available, the introduction of the Waterbury speed gear

between the motor and driving gear enables extreme flexibility. The electro hydraulic steering gear combines the advantages of the hydraulic steering gear with the efficiency and adaptability of electricity as a power source.

PIPE PRODUCTS.—The products of the Whitlock Coil Pipe Company, Hartford, Conn., consisting of apparatus formed from pipe and tubing, or parts so formed, are described in a conveniently referenced pamphlet issued by this company. The products are divided into four classes—bent and welded piping for high pressure steam and fluids, coils of pipe and tubing which are made continuous by welding or brazing together the required number of pieces, welded receivers for storing fluids under high pressure and tubular heat exchanging devices including many types of heaters and coolers for different purposes.

CENTRIFUGAL PUMPS.—Small single stage centrifugal pumps for motor or belt drive are described in a bulletin and an instruction manual issued by the De Laval Steam Turbine Company, Trenton, N. J. These pumps are made in 1½-inch and 2-inch sizes and are designed for capacities ranging from 5 gallons per minute against a 10-foot head up to 130 gallons per minute against a head of 150 feet. The bulletin contains complete tables and instructions for selecting pumps to meet different conditions and also explains methods of determining the proper speeds, the manner of selecting piping, valves, fittings and the most desirable type of drive, either pulley or motor, in order to secure an efficient and satisfactory installation.

FUEL OIL BURNERS.—The Morse fuel oil burning system and the combustion engineering service of the Morse Dry Dock and Repair Company, Brooklyn, N. Y., are detailed in a well illustrated catalog recently issued. By means of an outline of the work of the designers, D. J. Irish, and the advisory engineering staff of combustion specialists, together with the drawings and photographs showing the actual construction of the system, an excellent idea of the system and the efficiency obtained by its use are given. In addition, the permanent follow-up service which is provided with each installation insures the best results with this equipment in operation. For convenient reference there are included valuable tables relating to oil burning and boiler products.

WE GUARANTEE that of this issue, 4,900 copies were printed; that of these copies 3,916 were mailed to regular paid subscribers, 389 were provided for counter and news company sales, 193 were mailed to advertisers, 31 were mailed to employees and correspondents and 371 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 21,600, an average of 5,400 copies a month.

MARINE ENGINEERING AND SHIPPING AGE is a member of the Associated Business Papers, Inc. (A. B. P.), National Association of Periodical Publishers, Inc., New York Business Publishers' Association and the Audit Bureau of Circulation (A. B. C.).

Requests for change of address should reach us two weeks before the date of the issue with which it is to go into effect. It is difficult, and often impossible, to supply back numbers to replace those undelivered through failure to send advance notice. In sending us change of address, please be sure to send us your old address as well as the new one.

Defeating Its Own Object

THE award of the contract for the reconditioning of the *America* to the Brooklyn Navy Yard is so unfair to the repair plants that we are even able to quote no less a personage than the Honorable Edwin Denby, Secretary of the Navy, as decidedly opposed to such a practice. Secretary Denby in a letter to the *New York American* under date of November 8, 1921, in reference to the efforts of a certain Congressman from the State of Massachusetts to secure the job of reconditioning the *Leviathan* for the Boston Navy Yard said:

"A bid by a private firm is a guaranty of the performance of the work at a price named and within a time stipulated.

"A bid from a navy yard is the estimated cost of the work. If work is awarded a navy yard after an estimate, the actual cost of the work is charged, whether the same be greater than or less than the estimated cost. Estimates ordinarily run fairly close, say within about 10 percent; but in a big reconditioning job where the actual amount of work necessary can only be revealed after opening up the work and uncovering all defects, it is difficult to make an estimate that will fall within 10 percent of the actual cost.

"Furthermore, the stipulated time for performance of work for other departments of the Government must always be subject to the condition that urgent naval work shall take pre-

cedence even if such precedence causes failure to perform the other Government department's work within the time stipulated.

"As the total cost of reconditioning the *Leviathan* will probably run somewhere between six and eight million dollars, it will be seen that an estimate submitted by a navy yard would not give the Shipping Board the exact information which they desire as to cost and time of performance of this work. The necessity for economy is so great that the authorities of the Shipping Board do not feel that they could take the chance of overrunning the estimated cost by five or six hundred thousand dollars. They must have a guaranteed total expenditure."

As a comment on Secretary Denby's letter we might show many cases where the estimates on various repair jobs approach differences reaching far nearer 100 than 10 percent but taking his own figures that the navy estimate might easily be 10 percent under the actual cost we should like to point out in the case of the *America* that the guaranteed price of the Morse Dry Dock and Repair Company was less than 7 percent in excess of the navy yard estimate.

This award is a severe blow to the repair plants not only in the case of this one ship but in the precedent that it sets for the reconditioning of other vessels that have been authorized by the Shipping Board. The avowed policy of the board is to seek the advice and cooperation of private shipping interests and eventually dispose of its fleet, under the mandate of the Jones Act, to private capital. How is it going to accomplish this purpose, if the Government sets itself up in competition with the very interests that it seeks to foster?

Evaporators Versus Deadweight

THE savings that can be obtained by the use of an efficient evaporator system on shipboard, as explained by Professor Chapman in his article on page 197 of this issue, are startling to say the least. As his calculations are based on a full deadweight rather than a measurement cargo or, in other words, on voyages where every ton of reserve fresh water displaces a ton of paying freight, it should be noted that his figures do not equally apply to partially loaded ships.

However, as most vessels constantly seek full deadweight cargoes and often obtain them, the question arises as to why evaporators are used only to a very small extent on merchant ships today. We find from Professor Chapman's figures that a saving of \$39,360 per annum with a double evaporator

system and a saving of \$35,600 with a single evaporator system is possible on a 10,000-ton deadweight cargo vessel. It is interesting to note that this one saving is at least twice the amount that such a vessel would have received in subsidy under the Merchant Marine Act of 1922 had that measure become a law.

A still more striking comparison is furnished by the total yearly fuel oil bill for the same ship under the same conditions as published in an article on stevedoring costs in the February issue of this magazine. The annual fuel bill is given as \$72,500, so, if the owner can save \$39,360—54 percent of this cost—or over 100 percent of the fuel bill of an equivalent motorship through increased freight revenue by the use of evaporators, then it is time to inquire whether there should not be some one in the steamship organization whose particular function it is to see that a small saving in one department, such as the fuel consumed in operating an evaporator, is not more than overbalanced by a large loss in some other department.

Is it not the solution in this case that the engineer is not interested in operating evaporators which require considerable attention and apparently add to the cost of the engineering department? We say "apparently" for there are several other gains and advantages which may be credited to evaporators that affect engine room economy. Among these items may be mentioned pure feed water, elimination of boiler scale, increase in rate of boiler evaporation, less boiler blow losses and increased temperature of feed water. Surely this subject is worthy of investigation by shipowners who are not depending on the Government to pay their bills.

The Agamemnon and Mt. Vernon

THE decision of the Shipping Board to authorize the reconditioning of the *Agamemnon* and *Mt. Vernon* marks an epoch in the development of our merchant marine, for it assures us a North Atlantic passenger service equal to that of the Cunard and White Star Lines. And this is not all for the country-wide facilities that a liner company employs to solicit passenger trade are also available for obtaining freight and it may therefore be expected that the successful operation of the United States Lines will find employment for freighters to supplement its passenger vessels.

As we have pointed out many times before, the *Leviathan* could maintain only a one-way express passenger service. At least three fast vessels are needed to insure a regular schedule and the only ships that are both available and capable of making 23 knots are the *Agamemnon* and *Mt. Vernon*.

What is more, the Shipping Board has no authority to construct new vessels, an undertaking that would require several years. They can, however, by adding the *Agamemnon* and *Mount Vernon* to the fleet of the United States Lines greatly increase the probabilities of disposing of the entire line to a private enterprise. The reconditioned vessels would serve their purpose for several years and so make it possible through the development of business to construct new steamers of even a more modern type than any that exist today.

A year ago last January we published an analysis by Carl

E. Petersen, naval architect of the United States Lines, showing exactly what might be expected from these vessels in the way of financial returns. In this analysis revenues were estimated at a minimum and expenditures at a maximum and still the balance per annum after deducting expenditures and capital charges was found to be \$1,048,000 for the *Agamemnon* and \$1,298,000 for the *Mt. Vernon*.

These ships as well as the *Leviathan* should have been reconditioned long ago not only because they would have by this time paid back a large part of their reconditioning costs but also, and of more importance, because their presence in active service would have had a great moral effect in favor of our merchant marine on the American people.

The strength of our position in cargo carrying tonnage is still a long way in advance of our passenger carrying trade. "It seems safe to forecast," said Mr. E. H. Rigg, in his paper before the Society of Naval Architects and Marine Engineers in 1921, "that passenger ship construction will figure somewhat prominently in our bigger and best equipped yards during the next few years, particularly when it is remembered that a considerable number of ships now running would, but for the war, have been out of service ere this and they will need replacement just as soon as practicable." We believe that many shipowners have delayed action pending the determination of a definite Government policy and that the work just authorized on the *Agamemnon* and *Mt. Vernon* is significant as an indication that the time to balance our fleet of cargo vessels with the necessary passenger ships has arrived.

Definite Shipping Policy Still Under Consideration

THE failure of the ship subsidy bill, because of the antiquated rules governing debate in the United States Senate which left a majority of that body impotent in the face of a filibuster by a determined minority, apparently has left the Shipping Board and the administration without a definite policy for transferring the Government fleet to private interests, although one is promised in a few weeks. Probably it is just as well that the board has decided not to act too precipitately in view of the fact that the amount of available tonnage is now such that the recent increase in the export and import business can not be depended upon to maintain the present improvement which has taken place in the rate situation.

After it had become apparent that the bill was dead, Chairman Lasker of the Shipping Board had announced that a "novel and startling" plan for the disposition of the fleet would be made public in a few days and it had been officially stated at the White House that the policy of liquidation would be in effect long before the next Congress meets next December. Before the President and chairman left for Florida on March 5, however, some change occurred which led to an announcement that a committee of the board, consisting of Commissioners Lissner, Thompson and Chamberlain, had been appointed to study and prepare detailed plans "with a view to bringing about, without interruption of service, the passage of the Government's lines into private ownership, in so far as possible." Another committee, consisting of Vice-Chairman O'Connor and Commissioners

Benson and Plummer, is to make a survey of the physical condition of the fleet as a whole. The President and Chairman Lasker are also reported to be giving some consideration to matters of general policy while on their vacation trip in Florida.

In a general way, three courses are open. The first, continued Government operation of the ships until conditions become such that private shipping interests will be "glad to take them off the Government's hands," was about the only alternative suggested by the opponents of the subsidy bill. They ignored the fact that the present fleet is not properly balanced and would require additional investment as well as heavy expenditures for renewals, to maintain it as a going concern, while its competition would tend to prevent the development of private shipping. Such a plan is not regarded with any favor by the administration, which has no desire to continue to stand the losses inevitably connected with such operation. A second theory is that since the matured policy on which the administration has staked its efforts has failed, the Government should proceed to get rid of its white elephant as speedily as possible. The third, which seems to be the one on which the board is now working, lies between the first two. While representing no commitment to a policy of Government operation, it recognizes that it will be practically impossible for the board to liquidate in any short time and that many months, if not some years, will elapse before the Government is actually out of the business of owning and operating ships.

The Jones merchant marine act directs the sale of the ships only "as soon as practicable, consistent with good business methods and the objects and purposes to be obtained by this act." Also it requires the board to take into consideration conditions that would influence a prudent business man in the sale of property "which he is not forced to sell." It may be that Chairman Lasker's "startling" plan was the result of an impression that he was "forced to sell" but that more deliberation suggested other considerations, such as the necessity of maintaining present services and of properly balancing existing fleets before an attempt is made to sell them. It is hoped that new shipping companies will be organized to take some of the services now being operated under MO-4 contracts, but President Smull of the Emergency Fleet Corporation says that no attempt will be made to sell any of the vessels of the fleet now operated by the United States Lines singly until the fleet has been built up to the point of balance regarded by the board as necessary by the addition of the *Agamemnon*, *Mt. Vernon* and *President Buchanan*, and also the *Leviathan*, now in process of reconditioning. The *Leviathan* will be ready for service this season but work on the other vessels cannot be completed in time for use this season.

It is believed that at least 300 of the 346 steel cargo and passenger vessels now being operated in the berths established by the board will be needed to keep up the services on these routes and that when the board's policy has been definitely outlined an effort will be made to sell these ships which constitute the cream of the fleet, but it may be that further legislation will be considered necessary to make more attractive the terms upon which the ships can be sold or possibly to remove some of the present laws which restrict their success-

ful operation. Even after the detailed plan is announced a good deal of time would necessarily be required actually to complete the negotiations. At the basic rate of \$30 a ton comparatively few ships have been sold and the question as to how much below this figure the board would feel justified in going is one of the difficult problems before it.

The board has 320 lake-type ships, under 4,200 dead-weight tons, which are suitable for coastwise service and some of these may be sold to foreigners because they can not compete successfully with American ships in foreign trade. Conditions in the oil business may be such as to enable an early disposition of the 80 tankers owned by the board, and there are some 221 steel cargo vessels now tied up which are regarded as suitable for economical operation and salable, if there should be a demand for tonnage, but it is probable that some 400 of the board's ships will be classed as fit only to be scrapped.

The Situation

THE defeat of the ship subsidy bill has not turned out to be such a body blow as many of us expected. Both shipping and shipbuilding prospects are brighter than they have been at any time since the depression started in the fall of 1920. In shipping, the demand for coal, particularly from Germany where substantial contracts have already been placed covering the next three months, has resulted in an advance in freight rates and still further advances are almost certain to occur until additional vessels are sent here from abroad or more of our own vessels are placed in commission. Several coal cargoes have also been fixed for Italy and a few for South America which has also helped to give a much firmer tone to the market.

Passing to the grain market, we can derive considerable satisfaction from the fact that Congress did provide means to finance the farmers and these credits are bound to have a very favorable effect on shipping. We have enormous supplies of grain in this country which can undoubtedly be shipped abroad, if credits can be arranged. It is apparent that a brisk demand for grain would at least maintain if not advance the rates that the recent demand for coal has created.

In this connection we should not lose sight of the growing tendency to ship grain through the port of Montreal whenever that harbor is not blocked by ice. Canadian wheat would naturally pass through a Canadian port but, if the shippers of Montreal get control of the grain market by handling both American and Canadian wheat, they are bound to favor their own farmers whenever possible. Such opportunities actually have occurred; for instance, great quantities of wheat were shipped from Canada through the port of New York in bond during the month of March while our own elevators, and this is particularly true of Buffalo, were stocked to the overflowing point. Probably the tariff on wheat has a great deal to do with this condition as it is but natural for nations to retaliate against any obstructions to the free flow of commerce.

Nor does it appear that the fate of the subsidy bill has discouraged shipbuilding any more than it has shipping. Significant in this respect is the recent report of the Atlantic

Coast Shipbuilders' Association which gives a total of \$5,000,000 as the amount of work contracted for during the months of January and February. In addition to this, the report is authority for the statement that additional orders are in sight that will bring the total up to \$15,000,000 by the first of May.

Confirming to a large extent the encouraging viewpoint of the Shipbuilders' Association is the recent statement of the Bureau of Navigation of the Department of Commerce which reports a total of 302,047 gross tons now under construction as compared with 251,858 gross tons on January 1. But by far the most encouraging prospects of the near future lie in the authorized and pending contracts for conversion, repairs and reconditioning. Chief among the new contracts whose consummation has been authorized are the reconditioning of the *America*, *Agamemnon*, *Mt. Vernon* and *President Buchanan*. These vessels not only have a direct bearing on the welfare of our shipyards and repair plants but they also will have a tremendous influence on developing and maintaining a first class transatlantic American passenger service.

While on the subject of conversion and reconditioning we would like to call attention to a project on which Admiral Benson is working; namely, the conversion of idle Shipping Board vessels to motorships. Many of these vessels, as is well known, have good hulls but inefficient machinery installations. They are worthless as they are and we have every reason to believe that the Shipping Board will dispose of them—on condition that Diesel engines are installed—at prices that will make it possible to procure motorships in this country cheaper than they may be obtained in any other country in the world.

Diesel engines have proven their reliability and they stand in a class by themselves not as slightly more economical than a steam installation but, according to conservative estimates, they consume only from one-third to one-half the amount of fuel that the most efficient steamer will use. Many authorities think it a crime to use oil under boilers and there is little doubt but that the fixed charges on the additional cost of a motorship over a steamer is the main reason why this type of vessel has not been developed in this country as it has and is now being brought to the front in foreign maritime nations. We believe Admiral Benson is working on the right lines and that the elimination of this differential in first cost through the sale of Shipping Board vessels at nominal figures will stimulate the conversion of a large number of steamers to motorships.

The outstanding feature in new construction during the past year has been the building of coastwise passenger vessels. While a number of these contracts have been awarded nevertheless it is still a fact that the average age of our coastwise passenger ships is still much greater than either the demands of economical operation or the comfort of passengers would permit, if foreign competition were allowed. Of course the replacement of these vessels must occur sooner or later and it is our belief that delay in doing so is principally caused by the mistaken idea that cheaper contracts can be obtained in the future.

No one would contend that shipyards could go on indefinitely taking contracts at ruinous figures but owners

usually are reluctant to place new work until prices have shown an upward trend. Such information as has recently been given out by the American Steamship Owners' Association that the idle privately owned American tonnage has been reduced to 10 percent, as well as the common knowledge that the world's idle tonnage has been reduced by 2,000,000 tons in the last year, coupled with the demand that the partial failure of the Mexican oil fields has caused for tankers, the lack of passenger and refrigerator ships and the phenomenal growth of our coastwise trade ought to convince shipowners, particularly in view of the rising market in all commodities, that delay in replacement is bound to be a losing policy.

The shelving of the subsidy bill does not mean that American ships are to be left without Government aid. Chairman Lasker in a recent statement to the press called attention to the fact that the Jones Bill is still operative. And further the declaration in that measure that the Government is in favor of doing what it can to encourage the development of an adequate privately owned merchant marine is by no means idle talk.

As a matter of fact, the Government is in a position without further legislation to grant in many cases what amounts to very substantial virtual subsidies. We refer in particular to advantageous contracts with operators, loans for the construction of vessels with low interest charges, preferential railroad rates to goods shipped in American bottoms, sale of ships at such low figures that the fixed capital charges are practically eliminated, transportation of army and navy supplies and personnel on privately owned vessels, employment of a liberal policy of payment for carriage of mails, which is fully authorized by the Act of 1891, co-operation with the Bureau of Foreign and Domestic Commerce, commercial attachés and utilization of other Government functions, adoption of a uniform bill of lading, establishment of foreign trade zones, establishment of local agencies throughout the country similar to those maintained by railroads and, if possible, the making of arrangements with the railroads for connecting rail and water transportation and many other items, not to mention the use of the same ingenuity and efficient organization that is displayed in other American industries.

We are told that the Shipping Board is now at work preparing detailed plans with a view of bringing about, without interruption of service, the passage of Government lines to private ownership in so far as possible. In the meantime our sailors have been officially advised that the board will continue to operate all of its lines and that it is their duty to carry on in a manner which will make for confidence, efficiency and stability.

The important part of Commissioner O'Connor's message to the seamen, however, was also recently expressed by Mr. Frank C. Munson, president of the Munson Steamship Lines. It is the statement that the American public are actually becoming interested. They are increasing their patronage of American vessels and they are carrying back with them to the inland states a story of wonderful achievement and efficient service. Efficient operation and management we must all acknowledge are of far greater importance to shipowners than any patronage that the Government might bestow.

Does an Annual Saving of \$40,000 Interest You?

Analysis Shows Evaporators Can Save Half of Fuel Bill on Steamers Under Full Deadweight Conditions

By Lawrence B. Chapman*

EVAPORATORS are used only to a very small extent today on merchant ships for producing make-up feed and water for culinary purposes. The common practice is to carry make-up feed in the double bottom tanks; and when evaporators are actually fitted they are, as a rule, used only in emergencies or to supplement the supply of water from the tanks.

Under present trade conditions where most of the cargo ships are sailing with only partial cargoes, or for ships that carry cubic cargoes and are not loaded to the draft marks, the conditions mentioned above are probably economically sound. However, when trade conditions are such that full cargoes can be secured there is a distinct advantage in using evaporators instead of carrying make-up feed as will be shown in this article.

TYPES OF EVAPORATORS

There are a number of methods in use of operating evaporators on shipboard as follows:

1. One evaporator (single effect) using high pressure steam.

(a) Vapor from evaporator shell to main or auxiliary condenser.

(b) Vapor to distiller and distillate to hot well or tanks.

2. Two evaporators (double effect) using high pressure steam to the coils of the first effect evaporator. The evaporators are operated in series, the vapor from the first effect shell goes to the coils of the second effect evaporator where its latent heat is used in evaporating more water.

(a) Vapor from second effect shell to condenser.

(b) Vapor from second effect shell to distiller.

3. Double effect as in No. 2 but fitted with evaporator feed heater. The vapor from the second effect shell goes to feed heater where its latent heat is used in heating the evaporator feed (see Fig. 1). A distiller is seldom used with this arrangement; the condensate from the heater passes directly to feed tank—through a steam trap.

4. Double effect (low pressure type) using low pressure steam (auxiliary exhaust) in the first effect coils. A low vacuum is maintained in the second effect shell and a distiller condenser and air pumps are used.

5. Triple and quadruple effect evaporators.

Generally of the low pressure type.

Of the various arrangements mentioned above the first arrangement, consisting of one evaporator without evaporator feed water heater, is the general practice when evaporators are installed in the merchant service. The fourth and fifth arrangements are used in the Navy, where large quantities of low pressure auxiliary exhaust steam are available. These last two types are not to be recommended for merchant vessels because of their complications.

OPERATION OF DOUBLE EFFECT TYPE

Arrangement No. 3 should be used on merchant ships instead of the simple single effect evaporator. This type can be operated nearly as easily as the single effect type and the gain in economy is marked. Fig. 1 shows a diagrammatic arrangement of a double effect evaporator with feed heater.

Referring to Fig. 1, the high pressure steam at about 95 pounds absolute enters the coils of the first effect evaporator and evaporates salt water in the shell into vapor at a pressure somewhat above atmospheric. The condensate from the high pressure steam will leave the coils at a temperature slightly below that corresponding to 95 pounds or about 312 degrees F. Evaporators should be operated so that the condensate is not allowed to collect in the coils.

The heat of the liquid q_2 in the condensate is returned to the boiler through the feed tank and it should not be charged against the evaporator. The heat used by the evaporator per pound of steam is, where q_2 = heat in water returned to boiler and $q_1 + r_1$ = heat of water and latent heat of vaporization of steam entering evaporator.

$$q_1 + r_1 - q_2 = 294.5 + 890.9 - 282 = 903.4 \text{ B.t.u. per pound.}$$

The vapor from the first effect shell passes to the second effect coils where its latent heat is given up in evaporating more salt water. The distillate from the second effect coils at about 225 degrees F. drains to the main condenser or feed tank.

The vapor from the second effect shell passes to the evaporator feed heater where its latent heat is used in heating the feed water from 60 degrees or 100 degrees to 200 degrees F. The distillate from the heater should drain to the feed tank.

The raw water for evaporator feed is taken from the sea or from the discharge of the main circulating pump and after passing through the coils of the heater enters the shells of the first and second effect evaporators.

ILLUSTRATIVE PROBLEM

In order thoroughly to investigate the relative economy of evaporators, consider a ship with the following characteristics (see article by writer on page 71, February issue):

Length between perpendiculars = 420 feet.

Displacement = 14,600 tons.

Gross deadweight = 10,000 tons.

Speed = $11\frac{1}{2}$ knots.

Shaft horsepower = 2,980.

Geared turbine, watertube boilers, fuel oil.

Although the calculations used in this article are based on a 10,000-deadweight ton vessel operating on a 5,000-mile run, the figures given may be easily varied to suit any ship and any radius of action. In this case failure to use evaporators would cause an annual loss of \$39,360 in the case of a double effect system and \$35,600 in the case of a single effect system. This, of course, is based on the assumption of full cargoes, as the principal gain is due to increased freight carrying capacity. It would have to be modified in the case of measurement or partial cargoes but even then the increased boiler efficiency through the use of pure feed water is worthy of very careful investigation.

*Head of the course in Ship Construction and Marine Transportation, Lehigh University, Bethlehem, Pa.

Total steam per hour all purposes, excluding evaporators = 37,400 pounds.
 Boiler efficiency in service = 70 percent.
 Fuel per shaft horsepower per hour without evaporator = 1.00.
 Make-up feed (including water for drinking and culinary purposes) = 5 percent.
 Radius = 5,000 miles.
 Days on run = 19.
 Single voyages per year = 11.53.
 Pressure of live steam to first effect evaporator coils = 95 pounds absolute.
 Vapor pressure shell of first effect = 23 pounds absolute.
 Vapor pressure shell of second effect = 14.7 pounds absolute.
 Temperature of sea water = 60 degrees F.

DOUBLE EFFECT EVAPORATORS WITH HEATER

Allowing 5 percent make-up feed, the required output of the evaporator is,

$$37,400 \times 0.05 = 1,870 \text{ pounds per hour}$$

$$\frac{1,870 \times 24}{2,240} = 20 \text{ tons per day.}$$

With the calorific value of the fuel equal to 18,700 B.t.u. per pound, a boiler efficiency in service of 70 percent and 1.40 pounds of water evaporated by evaporators per pound of steam, we obtain,

$$\frac{18,700 \times 0.70}{903.4} \times 1.40 = 20.3 \text{ pounds of sea water, evaporated per pound of fuel.}$$

As already noted the heat of the liquid is not charged up against the evaporator as it is returned to the boiler via the feed tank. The above evaporation of 1.40 pounds of sea water per pound of steam is for a feed temperature of 100 degrees F. from the main circulating pump discharge. If an evaporator feed heater is used and the temperature of the raw water increased to 200 degrees F., the evaporation will be increased about 10 percent, giving $20.3 \times 1.10 = 22.3$ pounds of sea water evaporated per pound of fuel.

This evaporation, however, does not allow for the additional steam required for operating the evaporator feed pump. Allowing the salt feed water to be 50 percent in excess of that evaporated (which is the common practice to allow for blow downs), and allowing a lost head through the heater and piping of 35 feet, we have,

$$\text{Water horsepower of evaporator feed pump} = \frac{1,870 \times 1.50 \times 35}{33,000 \times 60} = 0.05.$$

Allowing 200 pounds of steam per water horsepower per hour for a small direct acting pump the steam used by evaporator feed pump is $200 \times 0.05 = 10$ pounds per hour.

$$\text{Steam per hour to first effect evaporator coils} = \frac{1,870}{1.40} = 1,340 \text{ pounds per hour.}$$

$$\text{Increase in steam consumption to allow for feed pump} = \frac{10 \times 100}{1,340} = 0.8 \text{ percent.}$$

Therefore the actual salt water evaporation per pound of fuel is,

$$\frac{22.3}{1.008} = 22.1 \text{ pounds of water.}$$

The total additional fuel oil required for working the evaporator plant is, $\frac{1,870}{22.1} = 85$ pounds per hour, or 17.3 tons per voyage.

For a voyage of 19 days the total make-up feed required would be $20 \times 19 = 380$ tons.

With fuel oil at \$1.55 a barrel and 338 pounds per barrel the cost of fuel for evaporating the make-up feed would be,

$$\frac{1.55}{338 \times 22.1} \times 2,240 = \$0.465 \text{ per ton of water.}$$

The increase in fuel per shaft horsepower per hour caused by using evaporator is

$$\frac{85}{2,980} = 0.03 \text{ pound per shaft horsepower per hour.}$$

This will make the total fuel per shaft horsepower per hour 1.03 instead of 1.00—an increase of 3 percent.

COMPARISON OF OPERATING EXPENSES WITH AND WITHOUT EVAPORATOR

(a) *Without evaporator*—(Make-up feed carried in double bottom).

Make-up feed water required per voyage = 380 tons.
 Net loss in carrying capacity per voyage = $380 - (10 + 18) = 352$ tons.

Weight of evaporator installation = 10 tons.

Weight of additional fuel for operating evaporators = 18 tons.

Cost of fresh water for make-up feed at \$0.30 per ton = $380 \times 11.53 \times 0.30 = \$1,320$ per year.

Loss in cargo revenue at \$10 a ton due to feed water carried = $352 \times 11.53 \times 10 = \$40,680$ per year.

Total annual loss caused by make-up feed = \$42,000.

(b) *With evaporator*.—(Double effect type with feed heater.)

Cost of evaporating per year at $46\frac{1}{2}$ cents per ton = $380 \times 11.53 \times 0.465 = \$2,040$

Interest, repairs and maintenance on evaporator plant (7 percent) = 350

Depreciation on evaporator (20 years) 5 percent = 250

Total annual operating charge = \$2,640

Annual gain due to use of double effect evaporator

$$\$42,000 - \$2,640 = \$39,360.$$

The cost of the 20-ton evaporating plant is made up as follows:

2 cast iron shell evaporators (with automatic feeders) ..	\$1,900
1 feed heater	1,500
1 distiller	700
1 evaporator feed pump	80
Miscellaneous piping and installation	820
	\$5,000

The double effect evaporator plant can be piped up so that it can be operated in parallel as two single effect 20-ton evaporators giving 40 tons per 24 hours, if required in an emergency.

The water for culinary and drinking purposes can be obtained from the coil drains of the second effect evaporator and no distiller or distiller circulating pump is necessary. A distiller, however, has been fitted for emergency use and piped up so that the distiller cooling water can be secured from the circulating pump of the main condenser. This eliminates the distiller circulating pump.

SINGLE EFFECT EVAPORATOR

(c) *With Single Effect Evaporator*.—If a single effect evaporator (with emergency distiller) is used without feed heater, the cost of the installation would be about \$2,500. One pound of steam at 80 pounds gage would evaporate only 0.78 pound of raw water. One pound of oil therefore will evaporate

$$\frac{18,700 \times 0.70}{903.4} \times 0.78 = 11.3 \text{ pounds of water.}$$

Fig. 1.—Diagram of Double Effect Evaporator Without Distiller

Correcting this for the consumption of the evaporator feed pump we have

$$11 \frac{11.3}{1.008} = 11.2 \text{ pounds of sea water per pound of fuel.}$$

The additional fuel required per voyage is

$$\frac{1,870}{11.2} \times \frac{24 \times 19}{2,240} = 34 \text{ tons.}$$

The increase in fuel per shaft horsepower per hour becomes 0.06 pound, instead of 0.03 for the double effect.

$$\text{Cost of evaporating make-up feed} = \frac{1.55}{338 \times 11.2} \times 2,240 = \$0.92$$

per ton.

Loss in carrying capacity by carrying feed-water = $380 - (35 + 10) = 335$ tons.

Without evaporator:

$$\text{Loss in revenue per year at \$10 per ton} = 335 \times 10 \times \frac{11.53}{100} = \$38,600$$

Cost of feed water per year at 30 cents per ton.....	=	1,320
--	---	-------

Annual loss by carrying feed water.....= \$39,920

With evaporator—(single effect):

Cost of evaporating make-up feed per year at 92 cents

per ton, $380 \times 11.53 \times 0.92$	=	\$4,020
Interest, depreciation and maintenance (12 percent)....	=	300

Total annual operating charge.....	≡	\$4,320
------------------------------------	---	---------

Annual gain due to use of single effect, $\$39,920 - \$4,320 = \$35,600$.

The single effect evaporator, therefore, shows an annual gain of \$35,600 as compared with \$39,360 for the double effect evaporator.

The above calculations show that there is a gain of \$3,760 a year in favor of the double effect evaporator as compared with the single effect evaporator.

CONCLUSIONS

The foregoing calculations show that when full cargoes can be secured there is a marked gain in annual income by using double effect evaporators in contrast to carrying make-up feed. Fresh water has been taken at 30 cents a ton which is the average cost in American ports. If water runs as high as 50 cents a ton, as it frequently does, the cost of water and evaporation are about equal.

When evaporators are used there are several additional gains and advantages chief of which are the following:

- (1) Pure feed water and the elimination of boiler scale which results in a higher boiler efficiency and reduced repair and cleaning charges.
- (2) Increase in the rate of evaporation in the boiler can be allowed due to the pure feed water.
- (3) Elimination of boiler blow losses.
- (4) Increase in temperature of water in feed tank due to high temperature of evaporator drips. In the above double effect installation the make-up feed enters the feed tank at about 200 degrees instead of 60 degrees. This increases the temperature of the feed and filter tank.

$$\frac{1,870 (200 - 60)}{38,750} = 6.7 \text{ degrees.}$$

With 250 pounds pressure and 100 degrees superheat at the boiler, the British thermal units per hour required are,

$$38,750 \times 1,264 = 49,000,000 \text{ B.t.u. per hour.}$$

The British thermal units increase at the feed tank is

$$1,870 \times (200 - 60) = 260,000 \text{ B.t.u. per hour.}$$

This results in a gain in plant efficiency of 0.5 percent.

OPERATION PRACTICE ON MERCHANT SHIPS

In order that evaporators function properly it is necessary that the salinity of the water in the shell should not exceed 3/32. This requires regular blow-downs either continuously or intermittently of about one-half of the amount evaporated. The general practice is to blow continuously and to fit regulator valves that maintain a constant level in the shell. This results in a constant salinity of about $2\frac{1}{2}/32$.

If self-scaling evaporators are used, such as the Reilly type with submerged coils, the coils can be kept free of scale by emptying the evaporator, according to their instructions, once each watch. When evaporators are operated on the above plan, double effect evaporators are as easy to take care of as the single effect type and the economy is practically double.

The condensate and distillate and drips from the coils should always be sent to the feed tank where the heat of the liquid can be saved. They should *never* be allowed to go to the main or auxiliary condenser.

Chamber of Shipping Discusses Maritime Situation

Recent Contracts for New Vessels in British Yards Unprofitable—Shipowners Faced With Additional Burdens—Shipping Depression Continues

By W. H. Wendon

THE past few weeks have produced topics of unusual interest to shipowners in the United Kingdom and abroad, for in the period under review the annual meeting of the Chamber of Shipping of the United Kingdom, the leading maritime body in the country, has been held. The subjects discussed have, as usual, been of importance befitting the occasion. Let us take, first of all, the situation which has arisen with regard to the recent placing of contracts for new vessels.

In the late autumn, it will be recalled, many shipowners took their courage in their hands and contracted for ships, presumably in the belief that the slump was ending, if, indeed, it had not already been passed. But it has since transpired that these contracts were placed at figures which—certainly from the point of view of shipbuilders, if not from that of shipowners themselves—precluded the contracts resulting in a profit. The position may be summarized as follows: There are shipowners who would not be averse to contracting for new boats in the neighborhood of £8 to £8 10s. per ton on the deadweight, but they definitely refuse to go higher than these quotations. Many contracts recently placed, it may be mentioned, were at figures between £8 10s. and £9 5s. If, then, shipbuilders are going to lose on the orders already placed, it is patent that, if contracts were accepted at owners' present views, the losses of builders would be still further increased, for in the meantime their costs of production have not materially diminished. This, then, must be held to account for the slackening off which has been apparent in the placing of new orders, coupled, of course, with the hitherto non-materialization of the "boom" in shipping.

SHIPPING DEPRESSION NOT YET ENDED

This method of reasoning is substantially on the lines of the arguments put forward by Sir Ernest Glover, the newly-elected president of the Chamber of Shipping, for at the gathering to which I have already referred he told his listeners that the first reflection which must occur to all is that the period of depression from which the shipping industry has been suffering for so long is not yet at an end. Twelve months ago the then president of the Chamber expressed the opinion that things were so bad that they could not very well get any worse, but the past year, in Sir Ernest Glover's view, has proved that, however deep the abyss may be into which shipping has fallen, there is always the possibility of the bottom of the abyss dropping out. Lest he should be thought to be exaggerating in making this statement, he gave the reminder that in several of the main trade routes of the world, rates of freight in 1922 were less than half the average rate of 1921, which was a bad year. On the other hand, there have been some reductions in running costs, but nothing which can compensate for such a fall in freights as has occurred. Taking the market value of ships today, and comparing it with the value even a year ago, Sir Ernest Glover fears that it must be recognized that there has been a very material shrinkage.

The new president's outlook for the future is not particularly rosy. He recalls that during last autumn shipowners saw a ray of light on the horizon, owing to an improvement in some markets, especially in the East, which had persistently maintained an attitude of extreme depression. This

improvement, and a reduction of shipbuilding costs, induced a good many owners to take heart and order new steamers. Builders were anxious to get work to enable them to keep their yards going and their staffs together, and no doubt they did accept work on very moderate terms, in view of the present level of costs of production—in fact, terms offering little or no prospect of profit. The hope of the late autumn gradually waned as the winter progressed, and Sir Ernest Glover ventures to consider that the outlook today is not nearly so promising as it was three or four months ago. Nevertheless, although his remarks may be regarded as pessimistic, he claims to be no pessimist. No shipowner, he holds, can be a pessimist. If he is, he must cease to be a shipowner. He believes in a sane optimism which does not under-rate the difficulties, but decides to meet them with courage and with a determination to win through, "and so reach the smoother waters which shipowners hope and believe lie ahead."

SHIPBUILDER DEPLORES BUILDING VESSELS AT A LOSS

Turning from the shipping position as seen through the eyes of a shipowner, it is not without interest to study the situation as it reveals itself to a front-rank builder of ships. Sir Alexander Kennedy, the authority to whom I am referring, is the chairman of the Northumberland Shipbuilding Company, Ltd., an important North of England concern, and his views at all times receive respectful consideration, both from his fellow shipbuilders and from shipowners. Apropos the present position, he does not mince matters. Frankly, he deplores what he describes as the tendency on the part of shipowners of expecting ships to be built at a loss, and he emphasizes the necessity for shipbuilders receiving reasonable remuneration for their work, pointing out the hampering effects of high costs of raw materials. He feels that at the present time the shipbuilding industry is at the cross-roads, and makes reference to "the slight flow of orders" in recent months—enough to give employers and workmen a chance to prove themselves. He maintains, however, that there is a definite limit to the extent to which shipbuilders can incur the risk—he might almost say the certainty—of loss.

Ships taken recently have been at prices which certainly cannot be repeated without a change of circumstances; shipbuilders, he says, have no desire to raise prices, but they cannot reduce them further in the present circumstances, or, he fears, for a long time to come. He feels that there is a tendency on the part of shipowners to place too heavy a burden upon shipbuilders and their workmen, and that there are some who expect builders to construct ships at a loss in order that they (the shipowners) may run the vessels at a profit. In conclusion, Sir Alexander Kennedy considers that, while the total price of ships has no chance of being further reduced for a long time to come, there must be an internal adjustment, "to give the builders a chance of receiving reasonable remuneration." It is not sound business, he says, to fill yards at present prices, nothing would be more disastrous than an appreciable rise in the price of new ships, and he trusts that, in spite of what has occurred on the Continent, coal owners and steel makers realize that an increase in the price of raw materials for the industry is bound to have a

hampering effect and completely stop any chance of trade recovery.

ADDITIONAL BURDEN FOR SHIPOWNERS PROPOSED

The shipowners of the United Kingdom are face to face with a new trouble revolving round what is regarded as an "economy stunt." The Board of Trade has framed certain definite proposals with a view to their being incorporated in a new Parliamentary Bill. It is proposed, *inter alia*, to raise the fees for tonnage measurement and for the yearly survey of passenger ships, and also to prescribe fees for signing on and signing off crews. The general effect of the proposals, it is felt, will be to shift the burden on to the shoulders of the shipowner from the Government Department concerned.

The Board of Trade recommendations arise from the "Economy Report" issued twelve months ago by the Geddes committee, dealing, among other things, with the mercantile marine services. One of the committee's recommendations was that the department should be rendered self-supporting by reducing the cost and charging shipowners additional fees in connection with the engagement and discharge of seamen. The report stated:

"The Mercantile Marine Offices were originally started in 1850 with the idea that they should be self-supporting by fees levied for engagement and discharge of seamen, but these fees, which amounted to, roughly, £70,000 in 1882, were abolished by the Board of Trade in that year. In 1892 Parliament took away from the Board of Trade their power to charge any fees in connection with engagement and discharge at a mercantile marine office. There is now no power, therefore, under the Merchant Shipping Acts to levy fees for the engagement and discharge of seamen in the United Kingdom, but fees are paid by the shipowner, if the engagement and discharge takes place on board ship at the request of the shipowner."

The total number of engagements and discharges of seamen per annum is approximately one million, and the committee recommended that the service should be rendered again self-supporting as it was prior to 1882 after certain steps had been taken for reducing the cost of the organization.

So much for this measure in broad outline. Shipowners resent the scheme whole-heartedly. Indeed, they feel serious apprehensions at the suggestion that, in addition to existing burdens, the shipping industry is to be saddled with the cost of carrying on an expensive government department, over the operations of which it has no control whatever. Shipowners point out that they pay very substantial fees for surveys, tonnage measurement, and so on, as a contribution towards the expense of this department, and they make no complaint of that. But they feel that they are entitled seriously to challenge the suggestion that these fees for surveys, etc., should, roughly speaking, be quadrupled, and that, in addition, the mercantile marine offices at the ports should be maintained by charging the shipowners 2s. 6d. for every man signed on or paid off.

It is estimated that the effect of the Government's proposals will be at once to throw an additional charge of about £400,000 per annum upon the shipping industry. Shipowners believe the principle upon which the Government is proceeding to be entirely wrong, and express the hope that it will think again before it places what they (the shipowners) deem to be so dangerous a precedent upon the Statute Book.

FOREIGN TAXATION OF SHIPS

Another matter which is receiving the close attention of shipowners is in regard to the taxation of ships in the countries to which they may happen to be trading. And this is a subject with which the United States is very intimately associated. It is conceded here that it is an unchallengeable fact that Great Britain in 1916 took the step of making foreign ships using her ports pay income tax. The immediate result was retaliation, and, from the British point of view, so serious has the matter become that two liner companies alone,

in the course of one year, paid no less a sum than £160,000 sterling in income tax to the United States Government.

In November, 1921, the International Shipping Conference, attended by delegates from every country possessing a merchant marine worthy of consideration, carried a resolution expressing, *inter alia*, "the desirability, in the interests of international trade, that legislation be encouraged in every maritime country in the world giving immunity from taxation in respect of the earnings of foreign shipping in all cases where such immunity is reciprocally given." In the same month the United States Defense Act became law, and contained a clause which gave effect to the principle for which the Chamber of Shipping and the International Shipping Conference had contended. The clause provided that no income tax should be payable in the United States of America upon profits of ships belonging to countries which gave similar exemption to the United States.

It is felt in United Kingdom shipping circles that this question of taxation abroad has reached such a level that steps should be taken to induce the British Government to accept what is generally regarded as America's fair offer. It is urged, moreover, that the Government would be well advised to accept the offer *now*.

One aspect of the matter which, in present conditions, is regarded as the most serious is that shipowners are taxed on profits beyond the measure of real profits, and even when real profits do not exist. It is emphasized that, unless this "pernicious" taxation system is nipped in the bud, a race may be seen between different countries as to who can extract the most from the shipowners. And the retaliation which may result from such a race may be easily pictured. The view of Sir Ernest Glover is that anything of the kind is much to be deprecated, and can only tend to hamper trade, while the increased costs being thrown on the shipowner must eventually be reflected in the rate of freight charged, to the prejudice of the country imposing such taxation.

WAGE REDUCTION OF BRITISH SEAMEN TO BE CONSIDERED

Every effort continues to be made to bring about reductions in steamship operating and working costs. There has, it is true, been an amelioration in dock and similar charges during the past year, but it is felt in shipowning circles that these reductions will not bear fruit in a revival of trade prosperity unless they are followed up by further substantial reductions in all charges incident to overseas transport. The item regarding which the greatest anxiety is experienced is in regard to wages. In the first place, British seamen's wages are still about 100 percent more than was paid before the war. It is, therefore, scarcely surprising that when, for example, dock workers are approached with a view to lowering their wages, they reply in effect: "Put your own house in order first"—in other words, bring down the wages of seamen.

This matter of reducing seamen's wages in Great Britain is to receive the serious consideration of those concerned, but it is appreciated that the position is an extremely delicate one. In this connection some remarkable statistics have been prepared by the Chamber of Shipping comparing the wages paid in this country and in Germany. Thus, the monthly wages and salaries of German officers and crew are as follows, the equivalent value in English money being given: First officer, £2 9s. a month, as compared with £18 10s. to £25 in this country; first engineer, £3 1s. 10d., as compared with £21 to £24 in this country; able seamen, £1 9s. 3d., against £10. Almost without exception, wages in Great Britain are the highest today in any maritime country in the world.

CONTINUOUS EMPLOYMENT OF SEAMEN DESIRABLE

An improvement in the method of employing seamen is one of the interesting subjects which have arisen during the past month. Sir Ernest Glover is responsible for bringing the matter to public notice. The system by which men are

signed on for the voyage is, he holds, eminently unsatisfactory, as employers never get to know anything of the men, and similarly the men know nothing of their employers. There is thus little or no chance of employers and employees taking a mutual interest in each other. But without an alteration in the law it would be impossible to make employment continuous, for not only is the sailor entitled to be paid off at the end of the voyage, but the owner is entitled to pay him off, and thus the practice has been established. Sir Ernest Glover, therefore, suggests the possibility of devising a scheme whereby employment might be practically continuous.

The difficulties which would certainly arise are not lost

sight of: For example, steamers, for some reason or other, might be laid idle for a considerable period, during which the crews would of necessity have to be paid off. It would, therefore, be necessary to have a clear understanding that men signing on would be available for working ships in port, and the scheme would have to be adopted by all shipowners, if success was to be achieved. The advantage to shipowners would, it is thought, accrue by saving riggers and shore gangs while in port, and, if reductions are to be made in wages, it is felt that the negotiations would be easier, if the reduction were coupled with some arrangement whereby the practical continuity of work could be relied upon.

Society of Naval Engineers Holds Annual Banquet

**Secretary Denby Outlines Salient Features of Naval Policy and
Secretary Hoover Urges Standardization of Business Methods**

THE annual banquet of the American Society of Naval Engineers was held at the New Willard Hotel, Washington, D. C., on February 27. Among the prominent speakers were Edwin Denby, Secretary of the Navy; Herbert Hoover, Secretary of Commerce, and Admiral R. E. Coontz.

In speaking of the work accomplished by the Navy during the past two years, Secretary Denby pointed out that it was the policy of the Administration to maintain our Navy at sufficient strength to protect our overseas possessions. The Navy, he said, exists to guard commerce and to provide national security. In addition to this, he declared it does a large amount of humanitarian work of which Smyrna is an example. The time of haphazard establishments and shore policies has passed, the Secretary said, and in its place great fleet bases have been built up.

Secretary Denby pointed out that the policy of keeping oil

underground for the future use of the Navy has resulted in many cases in the oil being drained off rapidly from neighboring fields. The Administration, therefore, had transferred the responsibility for an adequate naval oil supply to the Department of the Interior. Tank space has been reserved where oil may be placed in storage in order to insure conditions that would adequately serve the Navy in times of emergency.

FLEET MOBILIZATION

The grand United States Fleet has been created, the Secretary declared, along lines similar to that practiced by other nations and almost all vessels of any consequence have been included in this fleet.

We are trying, Secretary Denby said, to get a bill through Congress that will put our Naval Reserve on a fixed basis.

Annual Banquet of the Society of Naval Engineers at the New Willard Hotel, Washington, D. C., February 27

He was sorry to have to say that we had only a skeleton reserve at the present time. In regard to the enlisted personnel he thought there could be an amelioration of punishments in many cases. This subject he said has been given much study as problems concerning the enlisted men were very close to his heart.

RE-ESTABLISHMENT OF CREDIT AND TRANSPORTATION

Secretary Hoover spoke of the work that naval officers had done in assisting in the re-establishment of credit and transportation after the war. He said that they had called upon the Navy to detail some 30 or 40 officers and had then given these officers instructions that they wanted the seaports opened. Thousands of tons of material had been sent into foreign ports under the direction of these officers and in his estimation never had arrangements been made with more businesslike precision.

SIMPLIFICATION OF BUSINESS METHODS

There is a realization, declared Secretary Hoover, that there must be simplification in our business methods. We

have relied upon mass production but we need to make further progress in the replacement of parts which means a greater simplification.

The Navy gives a moral background, the Secretary asserted, that will provide the encouragement to undertake marine and commercial ventures. It gives a feeling of security to American commerce and is a cheap form of insurance.

60,000 MEN AT SEA

Out of the 86,000 men that Congress has allotted to the Navy, said Admiral R. E. Coontz, 60,000 are at sea. One of the greatest things in the world is morale and it was feared that the reduction in naval personnel would injure it but he was glad to say that it did not.

Speaking of the mobilization into one fleet, Admiral Coontz pointed out that the Commander-in-Chief was in this way relieved from many petty details and could exercise his brains on strategy. The Pacific ocean, he said, would be the most important in the future and plans had been made for a great base on that coast and other minor bases all the way down from Alaska to Hawaii.

A Survey of Philippine Shipping Conditions

American and British Ships Share Trade About Equally—Japanese Vessels Dropping Behind—Extension of Coastwise Law Discussed

By Vicente Villamin

LIKE Coue's formula for a happy life shipping conditions in the Philippines are getting better and better. More and better equipped steamers, both passenger and freighters, are now giving improved and speedy service. Healthy competition and the reviving foreign trade are the two determining factors in the situation.

The trade for 1922 amounted to over 359,000,000 pesos, registering a balance of approximately 25,000,000 in favor of the Philippines. The bulk of the trade was done with the United States, it being valued at 224,000,000 pesos, of which 28,000,000 was exports and 96,000,000 imports.

British ships led in the volume of the trade carried, the American coming a close second. Cargoes valued at 135,000,000 pesos were moved in British bottoms as compared with 132,200,000 pesos in American. In 1921 the proportion stood at 169,700,000 pesos British and 139,000,000 pesos American. Of a total of 1,272,779.77 tons engaged in ocean shipping, 448,971.42 was British and 405,273.01 American. It will be seen therefore that American vessels carried the largest volume of the trade on the basis of relative size of tonnage. In 1920 the American tonnage was 79,164.41, British, 399,094.56 and Japanese, 328,092.74. Of course, American vessels from 1918 to 1920 transported the bulk of the trade. Japanese vessels on the run are being pushed more and more behind.

HOW TRADE IS DIVIDED

Specifically taking up the trade between America and the Philippines, official figures show that during the first 11 months of 1922, 75 percent of the imports from the Pacific coast and 15 percent from the Atlantic Coast were carried in American vessels. Regarding exports, 67 percent to the Pacific Coast and 45 percent to the Atlantic Coast were carried in American ships. With the allocation by the Shipping Board of more tonnage to the Atlantic-Philippine trade American bottoms will undoubtedly take away proportionate cargo from the foreign lines.

During the period under review 956 first and 6,600 third

class passengers sailed from Manila to the Pacific Coast, including Honolulu and Vancouver. During the same period in 1921 there were 959 first and 4,571 third class. During 1921, 57 percent of all passengers traveled in foreign vessels and 43 percent in American vessels. In 1922 the position was reversed, being 54 percent for American and 46 percent for foreign vessels. Members of the Army and Navy are excluded. Their travel is taken care of by the army transport service. The showing of American passenger steamers cannot be but highly encouraging, especially in view of the fact that the most commodious and the fleetest liners on the run are the Empress greyhounds of the Pacific operated by the Canadian Pacific Steamship Company.

AMERICAN MAIL SERVICE PREDOMINATES

In connection with mail service, the United States Government paid during the fiscal year \$744,741 to American vessels and \$163,633 to foreign. The American payees were the Admiral line, Oceanic (Spreckles), Pacific Mail Steamship Company, the China Mail Steamship Company and others whose contracts amounted only to \$4,200; and the foreign were the Union Steamship Company, Toyo Kisen Kaisha, Osaka Shosen Kaisha, Nippon Yusen Kaisha, Canadian Pacific and others which received a total of \$17,545. It should not be overlooked that the payments were made for mail service between America and the entire Far East.

Besides Cebu and Iloilo new ports have been made ports of call for ocean-going steamers thus obviating expensive trans-shipment in Manila. In this service Shipping Board steamers lead. This is a matter of general congratulation.

During the past year steamers under the German flag took their places in the trade after an absence of eight years. A new line, the Hugo Stinnes Far Eastern Services, has been added. The Canadian Pacific placed two additional steamers on the Vancouver-Hongkong run, connecting with Manila by auxiliary service. Of the American, the Tampa Inter-Ocean Service Steamship Company, operating a monthly service, made its appearance. The Pacific Mail discontinued

its Manila-East India Line as well as the direct line between San Francisco and Manila via Honolulu as it was found unprofitable. It must be pointed out, in this connection, that 1922 was a poor foreign trade year.

THE PAN-PACIFIC COMMERCIAL CONGRESS

It is interesting at this juncture to recall that in November last an international gathering of prominent men from countries bordering the Pacific Ocean met in what is called the Pan-Pacific Commercial Congress in that sunny and romantic city of Honolulu. Of the various propositions brought forward to promote the best interests of the region the most ponderous, and incidentally the most indicative of the unsettled shipping conditions on the Pacific, was that offered by an American. This shipping connoisseur proposed to divide the wide ocean into zones, these zones to be allocated to the different maritime nations in order to control the size of tonnage in relation to the requirements of the trade in the respective zones and thus effect the elimination of unnecessary bottoms which increase operating and maintenance expenses and become a burden on commerce and trade. It appears to the writer that this fantastic proposition has served only to make the delegates overlook the fact that the biggest shipping question that can engage the minds of those interested in the Pacific trade is the proposed extension of the United States Coastwise Laws to the Philippines.

The Honolulu conclave which aimed at a rapprochement in amity, commerce and intellectual interest between the countries participating entirely missed the coastwise law question which is causing much dissatisfaction and speculation. The idea of internationalizing the trade and shipping situation in the Pacific, proceeding from the theory that trade is nationless and tribeless and thrives best where transportation is free and unshackled, will be blasted beyond identification. The Filipinos know of the anomalous fact that one can make shipments from San Francisco to Manila, for instance, more cheaply than he can from San Francisco to Honolulu despite the further distance of 4,000 miles to Manila. They know, of course, that by the operation of the coastwise law in Hawaii competition is eliminated, and its meaning is easily realizable.

DISTANCE A VITAL ELEMENT

The distance of the Philippines from the mainland of America is a vital element in the discussion of the wisdom or unwisdom of applying the law to that country. The Philippines is almost equidistant between America and Europe. Vessels originating from the Atlantic seaboard, with which the bulk of the trade is done, have longer voyages to make than those coming from European ports. The difference in ocean distance between the Panama Canal route and the Suez is only around 100 miles to the port of New York. When the freight is increased the tariff advantage which America and the Philippines enjoy from each other will be wiped off and the exports of America to that country will be subject to unnecessary ruinous competition from European and Oriental exports. This, of course, means the diversion of trade from America to Europe, a consummation stoutly to be prevented.

The only remedial measure is to raise the tariff wall around the Philippines (that country has a different tariff law than the United States). This might be desirable were it not that the result would be the raising of the cost of living in that country. This is one of the strongest reasons why the Filipino people are dead against the extension of the coastwise law to their country.

Manufacturers in the United States are opposed to the plan because the increased cost of transporting merchandise will either have to be absorbed by them or passed on to the ultimate consumers in the Philippines. Being unprepared to do the former they see that by making the consumers pay

will only result in the diminution of the demand and therefore a distinct loss to them.

Another thing that should interest American manufacturers who sell to the Philippines is that high freight rates will operate against Philippine exports and consequently impair the purchasing capacity of the country; while to those manufacturers who buy raw materials from the Philippines, advancing transportation and handling expense will place them at a big disadvantage in competition with manufacturers of similar products in foreign countries. To instance this assertion, high freight rates on copra, a tropical staple on the free list, will inevitably send it from the primary markets in the Far East to either Marseilles or Hull for crushing, and, also, the American coconut oil mills will be rendered idle. And shipments of oil from Europe to America will be resumed as in pre-war times. American oil crushers naturally are found to be in opposition to the law.

EFFECT ON MANILA

With regard to the effect of the law on the hope of making Manila a leading entrepôt in the Orient, opinions widely vary. The writer believes it will blast that hope completely. An American steamer leaving San Francisco, for instance, calls at Manila and then sails on to Batavia, Java. The same itinerary is followed on the return voyage. She can carry cargo between the three mentioned ports without contravening any law. On the other hand, a Dutch liner from San Francisco cannot carry cargo or passengers from that port to Manila and it would not be worth its while to make a detour to the latter port to pick up whatever business it could get for Batavia. The resultant condition would be virtually to confine the bulk of shipping between Manila and Far Eastern ports to American bottoms. There should really be no objection to that scheme were it not so inimical to trade in placing the Philippines on a non-competitive basis. The geographical position of the country in relation to America and the highly competitive nature of its products will affect very adversely its economic existence if it were to be placed out of joint in the scheme of commerce in the Far East by restrained transportation facilities.

From this point the discussion can go to the claim that by the American ships giving the "stoppage in transit" and "fabrication in transit" privileges to shipments out of Manila to surrounding ports the talk of making Manila the distributing point for American manufactured goods will be nearer to realization. The writer sharply differs from this view. Upon the precedent of comparative freight rate to Hawaii, it is not improbable that the rate from America to Manila would be higher than to, say, Batavia, Sourebaja, Saigon or Singapore, the difference in distance not being over 2,000 miles and the long haul making the steaming distance comparatively shorter. Besides, it is reasonable to expect that shipments from America to foreign ports in the Orient will be made in foreign flag steamers who can quote lower rates.

Certain maritime laws are simply constricting the life of the American merchant marine, which deserves to exist and exist in a fashion that is befitting the world importance of America. The coastwise law proposition as regards its extension to the Philippines which is separated from the mainland of America by the widest ocean in the world will tend to destroy the Philippine-American commerce and ultimately redound to the damage of the merchant marine itself.

FOR CONVERSION TO MOTORSHIPS.—Sidney Henry, Director of Sales, United States Shipping Board Emergency Fleet Corporation, announces that the steel tankers *Bidwell* and *Miller County* of 10,254 deadweight tons each, and the steel cargo *Challenger* of 11,850 deadweight tons, have been sold to the Sun Shipbuilding Company, Chester, Pa., for conversion to motorships.

Recent Developments in Marine Insurance

**Discouraging Outlook — Over-Insurance — “Sister Ship”
Salvage—War Rates—Towing—Barge Canal—“Collision”**

By “Bordereaux”

MARINE underwriters are considerably discouraged by the failure of the passage of the Ship Subsidy Bill, particularly as it comes at a time when many other factors are conspiring to restrict a prospect of profit in their business. They fear that the collapse of the subsidy campaign presages a lack of interest in our maritime affairs and may mark a declension of our merchant marine to a point of unimportance comparable to that of pre-war days. If it is true that insurance follows the flag, then the loss of our merchant marine holds out little hope for American underwriters, particularly as they are in daily active competition with a nation whose maritime affairs are its chief consideration and where the Government and the various branches of industry stand firmly behind all measures for the advancement of overseas trade.

With the conclusion of the first quarter of 1923 opportunity presents itself to permit of underwriters making a reasonably accurate survey of the outlook for the year. It is the judgment of the Street that 1923 will not result as satisfactorily as did its predecessor, comparing the actual underwriting outcome of each year. The principal reason for this anticipation is the forced lowering of rates to a point, in many instances, far below those of the pre-war period. One class of commodities after another has been subjected to average rate attacks, under spur of hungry competition, until it is impossible to name a single important class of merchandise or hulls which has escaped the raiding tactics. Premium at any price appears to be the slogan, even in what have always been regarded as conservative offices. It is a problem how long the situation can endure.

Still another influence that has a conflicting effect on the marine insurance business for 1923 is the increasing prosperity of the country. Strange as it may seem, marine insurance is both benefited and injured by a wave of prosperity at home. It is benefited in that when wages are high everyone has money to spend and there is a demand for commodities which greatly increase our import trade, thus augmenting premium writings on important business from abroad. And the insured values are higher, with a corresponding increase in premium volume, because prosperity generally means an advance in prices. But, unfortunately, there is often a reflex action in a rising tide of prosperity, that an increase in wages and commodity prices at home makes it more difficult for the American exporter to compete in foreign markets for the world's trade. Just now, in many cases, our exporters are finding increased difficulty in selling their products. This is notably true in the textile and other manufactured goods trade. If the English and German export markets were on a normal basis our export trade would feel this competition even more keenly than it does today. The only consolation that remains to the American underwriter is “the unexpected”; possibly relief may lie that way.

Over-Insurance

FROM time to time ill-formed parties break into print with protests against over-insurance of steamers by means of “honor” policies. This they pronounce a grant abuse of the system of P. P. I. coverage. These antics appear to be unaware of the fact that the underwriters have themselves adopted measures for the prevention of ex-

cessive sums being insured in respect of vessels by stipulating that the amount covered on disbursements shall not exceed 15 percent of the value of the steamer. Owners acting to the contrary are wasting both time and money, for if excessive insurance is taken out they would be unable to recover in event of loss.

“Sister Ship” Salvage

IN the past, difficulties have frequently arisen over the allowances which the Shipping Board has made to its own ships for salvage services rendered them. It is believed that trouble along this line will be obviated in the future through the good offices of a special committee that has just been appointed to act in an advisory capacity in this connection. The committee consists of George B. Ogden, chairman; Douglas F. Cox, William D. Winter, Hawley Chester and J. S. Gilbertson. Settlements arrived at by them will doubtless meet with general approval among underwriters insuring cargo in the vessels involved.

The regular Underwriters' committee recently attended a conference arranged with W. J. Love, of the Shipping Board, for the purpose of reviewing with the officials of that organization the arrangements for the handling of P. and I. claims. It found the Board most anxious to meet its proper cargo liabilities in a spirit of fairness and liberality. Mr. Love assured the committee that the Board stood ready to recognize all of its just liabilities and is prepared to provide machinery which will insure the prompt settlement of proper claims against it. The Board also expressed its readiness to confer with the committee representing the underwriters at all times for the purpose of adjusting any outstanding difficulties and smoothing the way for reciprocally satisfactory relations. When the subject of allowances came up Mr. Love showed a disposition to take a broad view of the matter and invited the formation of a committee to discuss with representatives of the Board the amounts to be allowed for “sister ship” salvage services, preliminary to the making of such awards. To this end the above-named committee was formed.

Barge Canal Hazards

AUTHORITATIVE estimates of the underwriting losses incurred on hulls and cargoes on the New York State Barge Canal last year fix the approximation in excess of \$700,000. The premiums scarcely passed \$200,000. In the light of such a disastrous experience the natural inclination of the underwriters is to abandon barge canal coverage altogether; and this they have determined to do unless the State will introduce substantial improvements for the safeguarding of floating property on that important waterway. And what the underwriters quote in the way of rates is something of prime importance, since it represents an overhead charge that will determine shippers to abandon the canal in favor of rail transportation. A co-operative movement is now under way, in which underwriters and transportation men have joined issues, and they have submitted, through a joint committee, a series of recommendations which Superintendent of Public Works Walsh proposes to make use of in an attempt to secure from the New York Legislature funds for

effecting the improvements indicated. The insurance men on this joint committee are Howard W. Beebe, chairman; Edgar E. Lethbridge and George C. Owens; and the transportation men are G. Roy Hall, of the Inter-Waterways Line; S. MacClinkan, of the Trans-Marine Corporation; and S. W. Bullock, of the Inland Marine Corporation.

Among the more pressing improvements recommended by this committee are the building of a new breakwater off the Eastern entrance of Oneida Lake to protect shipping against the northwest winds, the buoys of the North and Middle channels of the lake, and the installation of a system of storm signals at each end of the lake. It is a singular fact that whereas the rapid rises in the Mohawk River caused most of the losses in 1921, in 1922 the scene of disasters shifted almost entirely to Oneida Lake.

War Rates Reduced

WITH France making steadily increasing incursions into German territory the question of a possible war between those nations is frequently under consideration by underwriters, but the matter is not as yet in a position to cause serious anxiety. It is difficult to arrange an equitable basis for determining war rates because, as a matter of fact, there is no war, and any violation of the Versailles Treaty on the part of France is a different thing from an act of war. England, being nearer than we are to the seat of these troubles, is in position to act with the greater intentness and accuracy; and the Britishers are evidently complaisant as respects war possibilities. To this end their underwriters have recently made a substantial reduction in war rates, as follows: German steamers outward bound from German ports, 5 shillings; homeward bound, 7 shillings and 6 pence. Steamers of other nationalities, outward and homeward, 6 pence. These rates will have their effect in the American market, with the added consideration of how the delicate balance of scowling nations at peace may be adjusted to warlike activities.

Responsibility in Towing

BY a recent court decision a ship that undertakes a tow is held responsible if she abandons her tow in order to save herself and the towed vessel is later lost because of the exhausted condition of her officers and crew occasioned by their efforts while in tow. Under such conditions, also, the negligence of the towing vessel cannot be charged to her charterers, where the charter was not a demise, 284 Fed. Rep., 56. In this instance in court the Norwegian bark *Aggi* was undertaken to be towed by the steamship *Edgar H. Vance*, then under charter to W. R. Grace & Company, from San Francisco to Balboa, Isthmus of Panama. Action was brought by the underwriters on the lost *Aggi*. In view of the terrific storm that was raging when the tow began, and in the light of the evidence as to disregard of weather probabilities on the part of the master of the towing vessel, the latter was adjudged guilty of maritime negligence and his vessel was held responsible for the damage caused by the *Aggi's* stranding after she was abandoned by the *Vance*.

New P. & I. Agency

ON February 20 the new United States Protective and Indemnity Association went into active operation, with more than 100 agents on duty at the more important ports throughout the world. These agents have authority to settle claims up to a maximum of \$1,000; larger claims will be taken up by the home office. This is an offshoot of the United States Shipping Board, but it will do business with private owners as well. Its president is Nathan A. Smyth; vice president, in charge of domestic work, Capt.

I. L. Evans, director of the Sea Service Bureau and an expert in admiralty law; Capt. F. E. Ferris, formerly Shipping Board Commissioner at London, in charge of foreign activities; John Nichol, formerly of the Old Dominion Line head of the cargo department; Oliver C. Garvin, of the claims department of the Barber Line, in charge of personal injury; and F. D. Yott, former legal adviser to the American Red Cross in Europe, legal adviser for the foreign department.

The organization will handle business of a liability nature that is not usually covered under the straight marine policy the Protection and Indemnity Clauses being introduced, where desired, to effect this protection. In cases where owners desire to have all their liability covered under a single policy, it is advantageous to have this feature taken care of in the special clause.

It was formerly the custom for underwriters to assume under the Collision Clause only three-quarters of the collision liability and to assume none whatever for loss of life or personal injury or for damage to harbors, docks, piers, nor for damage to goods on board the vessel, nor for any other liability for which the owner might be held by law. The theory behind this action was that leaving one-quarter of the collision liability with the owner would have the effect of making him more diligent in seeing that his vessel was carefully navigated. Thereupon there arose clubs that undertook the insurance of these factors, and the result was that all the supposed advantages of leaving these risks partly on the shoulders of the owners were lost to the underwriters. Accordingly the three-quarters limitation has come to be usually omitted from the Collision Clause.

Court Definition of "Collision"

AFTER litigation extending over nearly three years, which one case was carried from the lowest courts to the highest in the State of New York, the Carroll Towing Company, Inc., has won out over the Aetna Insurance Company, and the word "collision" has received an authoritative definition, 196 N. Y. Supp. 698. Instead of meaning fortuitous contact between two vessels or other navigable objects, the court holds that "collision" means contact with or impact upon foreign bodies present in the water and is not restricted to mere collision with navigable objects.

Numerous court decisions were cited in support of the stand. One was the finding of Chief Judge Parker, 16 N. Y. 114; 57 N. E. 302, which was expressed as follows: "Collision, in its strict nautical and legal acceptance originally meant the impinging upon one another of vessels while being navigated, but in course of time and by common usage the application of the term has been so far extended in this country at least, as to include the impact of a vessel with other floating objects."

Judge Hough, in *Western Transit Co. vs. Brown* (D. C. 152 Fed. 476, said: "Neither is it denied that the word 'collision,' as used in marine insurance, can no longer be limited to that fortuitous contact of navigating vessels which is its obvious and natural signification."

SHIP SALES.—Eight steel tankers have recently been sold by the United States Shipping Board Emergency Fleet Corporation to the following companies: The *Hammac* of 9,980 deadweight tons to the General Petroleum Company, New York; the *Halo* of 10,078 deadweight tons to the City Service Company, New York; the *Tustem* and *Bohemian Club*, 9,799 deadweight tons each, to the Atlantic Refining Company, Philadelphia, Pa.; the *Devolente* and *Richconcal*, 10,000 deadweight tons each, to the Beacon Oil Company, New York, and the *Warwick* of 6,008 deadweight tons and the *Deroche* of 10,000 tons to the Union Oil Company.

Ann Arbor Car Ferry No. 3 Lengthened to Give 33 Percent Greater Car Carrying Capacity

THE Ann Arbor Railroad Company initiated the first lake car ferry movement known to transportation where sea operation was undertaken. The idea was conceived by them in 1890, and at that time they constructed two wooden car ferries, Nos. 1 and 2, which were placed in commission in November and December, 1892. These ves-

sel had a carrying capacity of approximately 24 freight cars, the cars being generally about 30 feet in length. The first steel car ferry, now known as the No. 3, was constructed and placed in operation in 1898, and in 1906 the No. 4 was put into service, the two wooden car ferries then being retired. In 1910 ferry No. 5 was built, and during 1917 ferry No. 6 was placed in commission. These vessels are so constructed and powered as to be able to navigate without difficulty during the winter as well as the summer months.

While the Ann Arbor Railroad Company established the first car ferry system on Lake Michigan in 1892, other railroads have since followed with service on several of the Great Lakes. Other points where long car ferry systems are now operated are on the Trans-Siberian, between Germany and Sweden, and by the Flagler system between Key West and Havana.

Ann Arbor car ferry No. 3, operating between Frankfort, Michigan, and Manitowoc, Wisconsin, recently left the plant of the Manitowoc Shipbuilding Corporation, where the vessel received extensive alterations. The ship was placed in a floating dry dock, cut in two, and lengthened 48 feet, giving it an increase in car carrying capacity of about 33 percent. The total length of the vessel is now 307 feet. New quarters for the crew were fitted on the upper deck in a new deck house, and increased passenger carrying capacity was provided.

NEW PROPELLING MACHINERY INSTALLED

During the lengthening operation, the old propelling machinery, consisting of two horizontal compound engines, and two natural draft Scotch boilers, were removed, and an entire new installation of modern propelling machinery was made. This consists of two triple expansion engines and two Scotch boilers 13 feet in diameter and 11 feet 6 inches long, carrying 180 pounds' steam pressure and operating under forced draft. The engines are of the vertical, three-cylinder,

direct-acting type, each developing 700 horsepower at 110 revolutions per minute and directly connected to outboard turning, four-bladed, solid cast steel propellers of sufficient weight to stand up under the severe ice conditions of winter service. As is usual on Great Lakes service, jet condensers are employed. The vessel is fitted with a very complete equipment of modern pumps, including ballast, feed, general service, sanitary and fresh water, and is lighted throughout by electricity supplied by two 10-kilowatt engine driven generating sets.

On her first trip after lengthening, the Ann Arbor No. 3

Lengthened Car Ferry No. 3 of the Ann Arbor Railroad

made the trip from Manitowoc to Frankfort, with 26 cars aboard, at a speed exceeding 13 miles per hour.

New Belgian Mail Ships for Service to Africa

Combined Passenger and Cargo Steamships Built to Relieve Heavy Traffic Demands to Belgian Colonies

THE combined passenger and cargo ships *Elisabethville* and *Thysville* put in commission a few months ago by the Compagnie Belge Maritime du Congo Mail-Boats were built and engined at Seraing, Belgium, by the Société Anonyme John Cockerill, to replace ships torpedoed off the French coast during the war. The increasing traffic demands between Belgium and her colonies in South Africa and along the Congo made necessary the addition of these two ships to relieve the other vessels of the Compagnie Belge Maritime du Congo Mail-Boats.

The principal dimensions of the steamship *Elisabethville* are:

Length between perpendiculars.....	440 feet
Breadth, molded	56 feet 10 inches
Depth, molded to shelter deck.....	37 feet
Draft	25 feet 3 inches
Gross tonnage	8,178
Displacement at load draft.....	13,250
Service speed	16 knots
Accommodations:	
First class passengers.....	180
Second class passengers.....	134
Officers	20
Crew	192
Total	526

The vessel is of the shelter deck type for carrying passengers and cargo and is classed 100 A-1 at Lloyd's under special survey. The watertight sub-divisions in the hull comply with the International Convention Regulations on Safety of Life at Sea. The ship has five decks. The watertight bulkheads are carried to the shelter deck and are fitted with doors operated both by hand and by the Stone-Lloyd hydraulic system. This system can be operated at the doors on either side of the bulkhead and from the navigating bridge.

The lifeboat capacity provides for every individual that will be carried. Welin davit equipment is supplied for all lifeboats.

PASSENGER ACCOMMODATIONS

Cabins for first class passengers are located on the bridge and shelter decks while the upper deck is devoted to second class passengers. The first class dining saloon is situated on the shelter deck forward of the engine and boiler casings and is reached by a double staircase from the first class lounge. Seating accommodations for 200 persons are provided. The second class dining saloon is situated on the same deck aft of the engine and boiler casings and has accommodations for 140 passengers. Other public rooms include first class lounge, first class smoking room, ladies' lounge and second class smoking room.

The first class lounge is in the shape of a large circular gallery lighted from above by a trunk, the ceiling of which is in the form of a stained glass dome embodying in design the signs of the Zodiac. Wainscotting panels and window frames are of polished oak, the curtain material used being mauve and gold silk. The uniformity of the panels is relieved by curved columns on which vases matching the urn-shaped light bearers at the four corners of the trunk are placed. The lounge is furnished with russet upholstered seats and chairs. In the space intended for the orchestra an allegorical oil painting forms an attractive background while against the surrounding panels sculptured panoplies of musical instruments are placed.

Leading from the lounge is the ladies' saloon ornamented

in the Louis XVI period. The panels in this saloon are of citron wood alternated with polished mahogany stanchions. Oil painted medallions framed with carved mahogany copied from masterpieces in the Brussels and Antwerp galleries adorn the walls. Window curtains and hangings are in gold and blue silk trimmed with design to match the uphol-

Well Over Dining Saloon

stery of seats and chairs which are trimmed with blue corded velvet.

A double stairway leads to the first class restaurant which is treated in white, the panels being relieved with decorated moldings. The furniture in the restaurant is upholstered in royal blue Utrecht velvet. The windows are decorated with cream moire and especially in the tropics a much appreciated effect of coolness is obtained.

The first class smoking room, situated on the bridge deck aft of the engine room is reached by a double flight staircase adorned with a stained glass window depicting the "Crocodile river" at Boma. The decoration of this space is of modernized Flemish style and the windows are framed with polychrome tiling. The center panel depicts the Halles of Ypres in a sepia tint while the others represent other Flemish landscapes. The furniture has antique leather coverings and the general effect is one of quiet and comfort.

Above the lounge is a series of staterooms with bathrooms adjoining. In these staterooms the furniture is of the Louis

S. S. Elisabethville: Interior Views. (1) Cabin de Luxe. (2) Captain's Cabin. (3) Wireless Room. (4) Galley. (5) Print Shop. (6) Hair Dresser's Shop.

XVI period of polished mahogany and matches the richly tinted carved panels and ceilings.

The same effect of luxury and comfort is carried out through the second class accommodations.

Throughout the entire ship the side lights and windows are fitted with mahogany blinds which are very essential while in the tropics for the same reason that those of the officers' quarters are fitted with mosquito proof copper wire gauze.

All of the woodwork and furniture was produced in the work shops at the shipyard.

PROPELLING MACHINERY

As noted the ships were engined by the Société Anonyme John Cockerill. The main propelling machinery consists of two sets of quadruple expansion engines developing 7,300 indicated horsepower which will give a normal speed of about 16 knots. The twin screws are of the built-up type each with three manganese bronze blades secured to the propeller bosses by Martin steel studs and gunmetal cap nuts. The bosses are of cast steel with cast iron cones fitted over the propeller nuts. All the main shafting is made of hydraulic forged ingot steel.

The ships are fitted with six Scotch single ended boilers working under a pressure of 215 pounds per square inch having a total heating surface of 14,100 square feet. These boilers were built by the Seraing Works of Cockerill and are arranged to work under Howden's forced draft system with two steam-driven fans.

AUXILIARY MACHINERY

The auxiliary machinery of the vessel includes the following:

Two circulating pumps of the centrifugal type, driven by compound engines, for circulating the water through the main condensers.

One auxiliary centrifugal circulating pump for the auxiliary contraflo steam condenser.

The feed pumps comprise two main double acting Weir pumps and one auxiliary double acting pump.

The evaporating plant consists of one Morison's radial evaporator with a capacity of 35 tons per 24 hours.

One general service pump of the vertical duplex type, which can be used for bilge suction, sanitary, feeding or circulating service.

One sanitary pump of the vertical duplex type.

One ballast pump of the vertical duplex type.

One fresh water pump of the vertical duplex type for washing and drinking purposes.

One distiller, Quiggin's Patent, with a capacity of 150 gallons per hour.

One underline hydraulic ash expeller of the Stone system.

The refrigerating plant consists of:

Two simplex vertical machines of Hall's type with a capacity of 4 tons of ice per 24 hours.

One CO₂ duplex evaporator.

Two independent brine pumps.

Two circulating pumps for the CO₂ condenser.

Total capacity of refrigeration chambers, 13,000 cubic feet.

ELECTRIC PLANT

Each vessel is equipped with three sets of 30-kilowatt dynamos driven by compound engines. An emergency unit, consisting of a 10-kilowatt dynamo driven by a Parsons type motor is installed.

The wireless equipment consists of two independent sets, one a quenched spark set having 1½ kilowatts capacity and the second a continuous wave set having 1½ kilowatts capacity. The maximum effective range of each set is 2,500 miles. The type of continuous wave set employed is particularly adapted to ship work because of its rugged construction, simplicity and rapidity of operation. Power for this transmitter is supplied by a motor generator on the upper deck and controlled from the wireless cabin. An emergency transmitter

is also installed, current being supplied from an independent accumulator battery of ¼ kilowatt capacity. This set has a main range of 220 miles.

The latest type Marconi direction finder is also installed. This instrument is used for taking bearings at a distance of 400 to 500 miles.

Derrick Barge Designed for Excavation Work

A GENERAL service derrick barge, designed for the Kelly Axe Manufacturing Company, Charleston, S. C., by Cox and Stevens, naval architects, New York, has recently been constructed by the Charles Ward Engineering Works, Charleston, W. Va.

The barge is primarily intended for excavating a lagoon at the company's works to form a harbor for the floating equipment owned by the organization. Later the barge is to

Derrick Barge Equipped with Steam Locomotive Crane

be used for loading and unloading steel material, for handling hickory logs obtained on the Tennessee, Cumberland and Green rivers and also for unloading barges at various points on these rivers where the finished products are delivered.

The length of the hull is 42 feet, the breadth 30 feet and the depth 5 feet. The draft when fully loaded is only 34 inches. The hull is of steel construction throughout, one end having a rake aft to facilitate towing. The opposite end of the hull is square and here two anchorage spuds have been placed.

The barge is equipped with one No. 4 type "H" Brown Hoist Company's steam locomotive crane with a structural base. The maximum reach of the crane boom, when in its lowest position, is 38 feet beyond the end of the hull. It has a capacity at 19 feet 6 inches radius of 22,250 pounds and at 57 feet radius of 5,200 pounds. The hull in the way of the foundation for this crane was made into a watertight

compartment to provide a fresh water tank for boiler feed water. On deck a portable coal box is provided having a capacity of 3 tons. When the fuel is to be replenished the coal box is swung ashore by the crane, filled and returned to its place on the deck.

Scout Cruiser Omaha Goes Into Commission

THE new scout cruiser, *Omaha*, the first of ten sister ships being built for the United States Navy, successfully completed her official trial on Puget Sound, and on February 24 was put into commission at the Bremerton Navy Yard.

As the highest powered vessel ever to sail under the American flag, this ship, with only one-half of the boilers in use, and these at only two-thirds of their capacity, went through the water at a speed that would take her across the Atlantic in less than four days. With all of the boilers in use a speed will be developed which would enable the vessel to cross the Atlantic in three days.

For two hours, as directed by the Naval Board of Inspection and Survey, headed by Captain Decker, runs were made over a measured mile course at $26\frac{1}{2}$ knots, and then for four hours a straight course was held from Tacoma to Port Townsend and back at a speed in excess of 27 knots, reaching $27\frac{1}{2}$ knots, or in excess of 31 miles per hour, for some of the time.

The ship was manned by a crew from the Todd Dry Dock and Construction Corporation, builders of this cruiser, and of two sister ships, the *Milwaukee* and *Cincinnati*, which will shortly follow her from the yard. No attempt was made to obtain the highest speed possible even with only half of her boilers in use, and in fact it was only required that a speed of 25 knots be maintained for the six hours.

The absence of vibration and motion usually associated with traveling on the water at 30 miles an hour was particularly noticeable. When at lunch, out of sight of the water, it was difficult to tell whether one were afloat or in a room ashore, except that there was no rumbling and shaking from passing trucks and trolleys.

After the completion of the trials the *Omaha* proceeded to Bremerton where Captain David S. Hanrahan, a noted destroyer skipper, took command with Lieutenant Commander H. T. Smith, who had spent some time at the builder's yard during construction, in charge of the engine rooms. A crew picked from the destroyer force came aboard and will be trained to operate the machinery and handle the ship in service.

In addition to the trial board, Captain Hanrahan, Lieutenant Commander Smith and other officers who will form part of the personnel, representatives of the builders of the ship, and of the machinery were aboard during the trial, and all expressed satisfaction with the performance and appearance of all portions of the work.

Designed for a speed of over 33 knots, the *Omaha* was built at Tacoma, Washington, by the Todd Dry Dock and Construction Corporation. There are 12 watertube boilers constructed by the Union Iron Works at San Francisco, equipped with Babcox and Wilcox fuel oil burners, each boiler capable of producing 125,000 pounds of steam an hour. This means that each hour all twelve boilers can turn 700 tons of water into steam, or more water than could be carried by ten of the largest locomotive tenders.

Each of the four propellers is driven by a 25,000 horsepower cross compound Westinghouse turbine and reduction gear. When at full speed the turbines revolve at 2,500 revolutions a minute, and this speed is reduced by means of the flexible frame gears to 370 revolutions per minute of the propeller shaft. At 26.4 knots it was estimated that the

propellers would revolve at 251 turns per minute; the actual trial came within less than one percent of this amount, showing the remarkable accuracy of the design.

The one hundred thousand horsepower installed for propelling this ship, besides being the greatest afloat under the American flag, makes this plant one of the most powerful for any purpose in the country. Few cities have power plants for lighting or operating the street railways of greater power.

A conception of the power of the *Omaha* is obtained by comparing it with our largest battleships with only one-third, and the mighty *Leviathan* with two-thirds the power installed in the *Omaha*.

It is not only important that these vessels be able to travel at express speed but they must be capable of going a great distance at the relatively slow speed of 10 to 15 knots. While the power needed at full speed will be 100,000 horsepower, at 12 knots it will only be 2,000, or 2 percent of the full power. In order to obtain a high efficiency at this small power cruising turbines are installed. These consist of small high speed turbines of the Westinghouse re-entry impulse type, with reduction gears which connect by means of a suitable clutch to the shafts of the main high pressure turbines.

By means of these cruising turbines it will be possible to operate the propelling machinery at 12 knots so efficiently that with a given expenditure of fuel the ship can steam over forty times as long, or fifteen times as far as at full speed.

Shipping Board Report on Foreign Commerce Issued

DIRECTOR R. T. Merrill of the Bureau of Research, United States Shipping Board, announces that the Bureau has completed its annual report of the water-borne foreign commerce of the United States, for the fiscal year, July 1, 1921, to June 30, 1922. This report shows the actual tonnage of cargo handled at the port, the amount and character of the principal commodities and their ports of destination, and origin. A previous report issued by the Bureau covered the cargoes entered and cleared at the principal ports of the United States, but did not show the ports of original loading or final discharge and therefore could not serve as a criterion of the actual port activities.

This report applies solely to trade between the United States and foreign countries, and is compiled primarily to aid the Shipping Board in its task of building up American flag services on essential trade routes. Because it does not include coastwise or intercoastal movements, it cannot be taken as a measure of the total activities of the individual ports. This is especially true of the ports having large coastwise movements and a small amount of foreign trade.

The growth of the intercoastal business, supplementing our already large coastwise trade, has been phenomenal and is especially noteworthy in the last six months. Were the figures of this movement included, there would be marked changes in the standing of many ports, particularly those of the Pacific coast.

Another feature of interest is the standing of certain ports due to one, or at the most two, predominating commodities. For example, it will doubtless be surprising to see Port Arthur, Texas, standing in the position it occupies. This rank is due wholly to its trade in petroleum, most of which, during the period shown, came from the Mexican fields. Later developments in oil production are tending to shift the center of production from the Mexican fields to southern California and, although a large part of its output will move to the East Coast by water, it is probable that a sufficient quantity will be exported from the Pacific fields to foreign countries to change markedly the standing of southern Californian ports in the next year.

One of the Shipping Board's 535-Foot Passenger Steamships

Performance Standards Established by Shipping Board for 535-Foot Passenger and Hog Island Cargo Vessels

THE Fuel Conservation Committee appointed by Vice-President Joseph E. Sheedy of the United States Shipping Board, which consists of Captain C. A. McAllister, Captain R. D. Gatewood, (C.C.) U. S. N.; Colonel George Bartlett, E. H. Peabody, D. M. Myer, Major G. M. Talbot, Maurice Healey, F. B. Webster, and C. J. Jefferson, head of the Fuel Conservation Section, is continuing the work of establishing the standards of performance for the active vessels of the United States Shipping Board fleet. The methods employed in establishing these standards were outlined on page 783 of our December, 1922, issue, the first set of standards established being for the 502-foot ships.

The standards for the 535-foot passenger vessels and also for the large fleet of cargo vessels built by the American International Shipbuilding Corporation which are referred to generally as the Hog Island vessels have been completed and

are being used by the various operators as a means of determining the efficiency of performance of the vessels of this class which they are operating.

535-FOOT PASSENGER VESSELS

The 535-foot passenger vessels have been subdivided into three classes and a set of performance curves developed for each class. These curves give the miles per ton of fuel which the vessel should make at a given draft and speed with moderate weather and average bottom conditions. They do not, however, represent impractical theoretical values but rather the values that have been obtained by several of the vessels of the class with the equipment and operating personnel working efficiently.

All of the 535-foot passenger vessels have the following characteristics:

Hog Island Type Cargo Steamship

Performance Standardization, 535-Foot Passenger and Freight Steamships

S. S. President Taft, President Pierce, President Grant, President Cleveland, President Jackson, Pan America, Western World.

Length overall	535 feet
Breadth	72 feet
Depth	50 feet
Loaded draft	30 feet 7 inches
Deadweight tonnage.....	11,310
Speed, knots.....	17.5
Engines.....	2 cross compound turbines
Boilers.....	8 watertube or tubular

The first of these three classes consists of the steamships *President Taft*, *President Pierce*, *President Grant*, *Pan American*, *Western World*, *President Cleveland* and *President Jackson*. These vessels are all fitted with similar propellers. The first five were built by the Bethlehem Shipbuilding Corporation, and are equipped with Fore River turbines and Yarrow boilers. The last two were built by the Newport News Shipbuilding and Dry Dock Company, which also built the turbines for these two vessels. These have Babcock and Wilcox watertube boilers.

The second class consists of the steamships *President Harding*, *President Roosevelt*, *President Madison*, *President McKinley*, *President Wilson* and *President Lincoln*. They were built by the New York Shipbuilding Corporation and have similar propellers and are equipped with Fore River turbines and Babcock and Wilcox boilers.

Performance Standardization, 535-Foot Passenger and Freight Steamships

S. S. President Harding, President Roosevelt, President Madison, President McKinley, President Wilson and President Lincoln. Built by New York Shipbuilding Corporation and equipped with Curtis turbines.

Performance Standardization, 535-Foot Passenger and Freight Steamships

S. S. President Jefferson, Southern Cross and American Legion. Built by New York Shipbuilding Corporation and Equipped with Westinghouse turbines.

The third class consists of the steamships *President Jefferson*, *Southern Cross* and *American Legion*. These three were built by the New York Shipbuilding Corporation and are fitted with Westinghouse turbines and Babcock and Wilcox boilers.

From the tabulated performance of these vessels it was found that the efficiency of performance varies from 98.8 to 62.7 percent for the various vessels. Eight of the 16, however, showed over 90 percent efficiency and all except two, which on their earlier voyages were subjected to inefficient and poor operation, showed over 80 percent, the average for the entire class being 87 percent.

The general average performance for all the 535-foot passenger vessels, as shown by this tabulation, is as follows:

Draft	R.P.M.	Observed speed, knots	Tons fuel per 24 hrs.	Pounds fuel per mile	Knots per ton		
					A, Actual	B, Theoretical	A Correction Factor
24' 5 1/8"	113.9	16.9	133	725	3.08	3.54	0.870

HOG ISLAND CARGO VESSELS

The standards for the Hog Island cargo vessels are of greater interest to the average operator as they are applied to the type of vessel which is the backbone of the merchant marine, for, after all, it is the cargo carrier which affects the greater part of our population, as this type of vessel carries the products of the Middle West, the products of the manufacturing centers and, in fact, the greater part of the whole country's foreign commerce. It is essential that these vessels be operated efficiently, if the American merchant marine is to be made possible.

The tabulation of the performance of these vessels shows efficiencies from 58.7 to 107.8 percent with an average of 83.67 percent for the entire class. The vessels of this class are practically identical and have the following characteristics:

Length between perpendiculars.....	390 feet
Breadth	54 feet
Depth	32 feet
Loaded draft	24 feet
Deadweight tonnage	7,840
Speed, knots	11
Engine.....	1 General Electric turbine
Boilers.....	3 Babcock and Wilcox watertube

Why should there be such a difference in the efficiency of performance? It has been found, as the individual cases have been taken up by the committee, that it generally hinges on the efficiency of the operating personnel and the attention which has been paid to the details of operation. In the one

case, the vacuum system is tight and the vessel is developing full power with minimum fuel. In the other case, there are leaks in the system and the power falls down and the fuel consumption goes up. It is a problem of correcting details which must be met by the operating force and the attention which is paid to these details is reflected immediately in the efficiency of performance.

An example of this can be taken from the tabulation compiled by the committee. The worst performers immediately became problems for the committee to attack and it is gratifying to note that the worst performer has shown on a voyage completed since the standards have been put into effect an increase in efficiency of approximately 30 percent which gives this vessel a rating somewhat above the average of her class.

The general average performance of 70 Hog Island type cargo vessels, as tabulated by the committee, is as follows:

Draft	R.P.M.	Observed speed, knots	Tons fuel per 24 hrs.	Pounds fuel per mile	Knots per ton		Percent efficiency
					Actual	Theoretical	
21' 8 7/16"	80.6	10.33	29.14	26.33	8.51	10.17	83.67

The figures and curves cannot in themselves increase the efficiency of performance of the various vessels, but they do give the operators a definite target to shoot at and, in attempting to hit the standard, the increased efficiency and reduced fuel bill will be accomplished; in that way they serve their purpose and help to maintain an American merchant marine.

INSTRUCTIONS FOR USING PERFORMANCE STANDARDIZATION CURVES

The curves on the performance charts show the number of nautical miles that a ship should travel on a ton of fuel for various speeds and drafts, and have been adopted as a standard for the ships as designated.

In arriving at this standard, due consideration was given for the increase in power required to drive the ship at sea over that required under trial trip conditions, and the increased steam consumption of the machinery at sea over that on tests. It is not expected that the ship will do as well on every voyage, as the curves show, as rough weather would decrease the mileage, yet in smooth seas the showing should be better, and the average performance should be equal to the standard, providing the ship and equipment are in proper condition, and properly operated.

The procedure for obtaining the performance of a ship on a voyage is as follows:

Divide the distance (in nautical miles) traveled by the fuel (in tons) consumed. This will give the actual nautical miles per ton of fuel.

Performance Standardization, Type "A" Steamships Built at Hog Island, and Equipped with Curtis Turbines

From the chart find the standard nautical miles per ton of fuel for the draft and speed on this voyage as follows:

On horizontal base line pick out average speed of voyage and run up this line in vertical direction until it intersects the curve corresponding to average mean draft, from this point follow over on horizontal line to read the miles per ton of fuel which represents standard performance.

Divide the actual performance by the standard and multiply by one hundred. This will give the percentage performance for the voyage.

Example: To find the percentage performance of a ship on a voyage.

For this we will take one of the 7,500 deadweight ton ships built by the American Shipbuilding Corporation, known as Hog Island type "A" ship.

Mean draft on leaving port.....	24 feet 0 inches
Mean draft on arriving.....	23 feet 0 inches
Mean draft on voyage.....	23 feet 6 inches
Distance traveled	3,000 nautical miles
Fuel consumed	310 tons
Speed	10.2 knots

Actual nautical miles per ton of fuel $\frac{3000}{310} = 9.68$.

Standard nautical miles per ton of fuel for 10.2 knots and 23 feet 6 inches draft (from curves) = 9.95.

Percentage performance = $\frac{9.68 \times 100}{9.95} = 97$ percent.

Improvements Made in Welin Marine Type Mills Releasing Gear

THE Welin marine department of American Balsa Company, Inc., Long Island City, N. Y., has recently succeeded in still further simplifying and making more reliable the Mills releasing gear, which has been on the market for twenty years. The number of parts has been reduced by so designing the supporting plate that it also acts as a guide for the eye of the block or shackle, thus making an end deck and guide casting unnecessary. In this new design all of the parts subjected to strain are made of wrought material and, as a result of this, the new design complies with the rules of the British Board of Trade as well as with the rules of the United States Steamboat Inspection Service.

End and Side Views of Gear in Locked Position

End and Side Views of Gear Unlocked for Release of Boat

These improvements in the Mills releasing gear have accomplished:

1. A gear with reduced number of parts and, because of this, of less cost to manufacture.
2. None of the parts subjected to strain is made of cast material.
3. A gear that is simple to install and easy to operate.
4. A gear with limit stops which make it positive of action.

This new type of gear is adaptable to installation in any type of lifeboat and, for the sake of safety, releases only when the boat is water-borne.

Vessel Tonnage Turned Out in Great Britain the Lowest in 30 Years

BRITISH ship production during the year 1922 represented a shrinkage of 50 percent since 1920, and made the poorest record for more than 30 years, says Commercial Attache W. S. Tower in a report to the Department of Commerce. The British merchant fleet is now only slightly larger than it was in 1914. About 98 percent of the increase in world tonnage since 1914 has been under flags other than British, and from controlling close to 45 percent of world merchant steam tonnage the British share has dropped to about 33 percent.

The course of ocean freights and time charter rates explains the reluctance to acquire more tonnage. The average ocean freight rate for 1922 declined 20 percent from the average for 1921, and the average of time charters showed a decline.

Prices for 7,000 to 9,000-ton ships, according to recent contracts, are said to range for £8 10s. to £9 10s. per dead-weight ton, a drop of at least £2 per ton since July, £4 per ton since January, and close to £10 per ton in the last 18 months. The reduction has been made possible largely by drastic wage cuts and by lower prices for materials.

Vessels entering British ports with cargo during 1922 show a tonnage increase of 15 to 20 percent over 1921. For clearances with cargo the showing is far better, the average monthly tonnage in the last quarter of the year being almost 40 percent larger than for the corresponding period of 1921.

This increase of activity was promptly reflected in a decrease of idle tonnage in British ports. The decrease from quarter to quarter since July 25, 1921, is shown in the accompanying table.

TONNAGE OF VESSELS LAID UP IN BRITISH PORTS

Date	British Flag		Foreign Flag		Total	
	No.	Net tons	No.	Net tons	No.	Net tons
July 25, 1921.....	883	1,650,788	140	201,624	1,023	1,852,412
October 25, 1921.....	654	1,158,425	88	137,811	742	1,296,236
January 1, 1922.....	621	1,179,548	91	128,045	812	1,307,593
April 1, 1922.....	422	734,240	62	102,379	484	836,619
July 1, 1922.....	533	1,025,662	50	86,670	583	1,112,332
October 1, 1922.....	419	752,469	37	72,155	456	824,624
January 1, 1923.....	371	671,886	40	60,312	411	732,198
(Preliminary)						

Propelling Machinery of the New White Star Liner Doric

MUCH interest is being manifested in steamship engineering circles over the engine equipment of the new *Doric*, which is now completing at the Harland and Wolf yards at Belfast to enter the service of the White Star Dominion Line between Montreal and Liverpool. The *Doric* is scheduled to start her maiden voyage from Liverpool on May 11, and will sail on her return trip from Montreal May 26. She is a sister ship of the *Regina* and *Pittsburgh*, both completed in 1922, and like the other two was built particularly for the one cabin passenger trade. Her gross tonnage is 16,500, and length and breadth 600 feet and 68 feet respectively.

The *Doric's* main machinery consists of two sets of Brown-Curtis single reduction geared turbines driving one port and one starboard propeller. Each set comprises one high pressure turbine which exhausts to one low pressure turbine and thence to the condenser. The power is equivalent to about 4,500 horsepower for each, thus making a total for the ship of about 9,000 horsepower. An astern turbine is incorporated in the low pressure casing.

The ahead and astern control or maneuvering wheels are mounted on the high pressure turbine. It is interesting to note that all the bearings are worked under forced lubrication, and in the case of the gearing the oil is discharged through sprayers onto the teeth. Should the supply of oil fail through any cause, the steam from the boilers is immediately checked by the operation of a patent governor, which also shuts off in the case of excessive rotor speed.

The rotors of these turbines are each connected to its pinion by a flexible coupling, and the pinions mesh with the main gear wheels mounted on the main or propeller driving shafts. The rotors have speeds of about 1,640 revolutions per minute at the high pressure and 1,400 at the low pressure, which correspond respectively to peripheral speeds of 365 and 472 feet per second. As the propeller revolves at a speed of 100 revolutions per minute this gives a reduction from the high pressure turbines to propellers of about 16½ to 1. The main gear wheels, 12 feet in diameter, weigh about 36 tons each, and contain 671 teeth of 7/12-inch pitch cut in double helical style in order to neutralize end thrust.

The outside dimensions of the complete gearing are 11 feet by 14 feet by 15 feet, and the total weight amounts to 74 tons. The teeth of one gear wheel are cut at an angle of 30 degrees on a specially constructed machine, and the operation took altogether a full month to complete. To obtain a good face of tooth it was necessary to keep the machine running continuously day and night, as a stoppage might cause an imperfection in the cut of the wheel and thus affect its contact with the pinion.

Each of the vessel's low pressure turbines weighs about 40 tons. It is interesting to note that in the four turbines there are 35,500 phosphor bronze impulse blades, which, if placed end on end, would extend for a distance of three miles. The rotors are of forged steel, the casings of cast iron, and the plates for directing steam on to the moving blades are of nickel steel cast into an iron frame or diaphragm. Steam is supplied from the boilers at a pressure of 215 pounds per square inch.

Outboard Profile of Steamship President Buchanan as She Will Look After Reconditioning

The Reconditioning of the President Buchanan

Unusually Complete Plans and Specifications Prepared to Convert
Ex-German Liner Into One of the Largest of Cabin Class Vessels

THE *President Buchanan*, built in 1907 at the shipyards of Harland and Wolff, Belfast, is to be converted into one of the largest and best cabin ships afloat. The specifications and plans prepared by the Gibbs Brothers, New York, who performed the same task on the *Leviathan*, are so complete that little or nothing will be left to the imagination of the successful contractors. As will be seen from the illustrations, the drawings are of the working rather than the contract type, which means that a great saving will be made in the time that it will take to do the work.

The work on the *President Buchanan* is looked upon as the most extensive reconditioning job brought out so far this year. The bids on the work are expected to be opened on April 2 and it will then probably take from 128 to 180 days to complete the job. It will be noticed from the outboard profile that the appearance of the ship will be changed considerably as the bridge house has been elongated necessitating the removal of two masts.

The amount of money required to convert this steamship into a revenue paying vessel capable of carrying 2,141 passengers will probably be well over \$1,000,000. Even a brief perusal of the principal changes to be made as outlined below will convince anyone of the magnitude of the undertaking.

REMOVAL OF EXISTING ACCOMMODATIONS

The whole of the existing joiner work, furniture, fittings and fixtures of the original first, second, third and fourth class passengers and of the officers and crew accommodations will be renewed. This includes all public rooms, staterooms, open berthing spaces, lavatory and toilet spaces, dining saloons and messrooms, galley and pantry compartments, hospital spaces, storerooms, etc. The ship's dry and wet provision storerooms, however, on *H* deck will be retained and reconditioned.

New accommodations for all cabin passengers will be constructed and equipped. They will be fitted out completely and extend from *A* to *G* decks. This will consist of about 200 two-, three- and four-berth rooms, a social hall and writing room, a ladies' saloon, a smoking room, a veranda, a gymnasium, a dining saloon seating 380 persons, lavatory and toilet spaces and bathrooms including 12 private baths, a galley, a pantry, two bakeries, a bread room, a butcher shop, deck stewards and service pantries with direct access to main pantry.

The existing main stairway from frames 114 to 118 will be replaced with a stairway of different type which will

permit it to be fitted with fire-resisting inclosures on the several decks, and an additional main stairway will be constructed from frames 90 to 96 running from *G* to *A* decks and fitted within a watertight inclosure on *E* deck and fire-resisting inclosures on *A*, *B*, *C*, *D* and *F* decks. Fire screen bulkheads of approved construction will be fitted within this accommodation, their spacing not to exceed 130 feet. The engine and boiler casings passing through this accommodation will be efficiently insulated.

NEW THIRD CLASS PASSENGER ACCOMMODATIONS

The new accommodations for approximately 1,424 third class passengers will be constructed and fitted out completely in the space extending from *D* to *G* decks. They will consist of approximately 364 two, four and six berth rooms, 3 general rooms, 2 smoking rooms, a dining saloon in six sections having a seating capacity of 700 persons, combined lavatory and toilet spaces, bathrooms and washrooms, laundries, a galley, a pantry, an auxiliary pantry, two hospital compartments with bathrooms attached, an operating room, a dispensary, two isolation hospitals with bathrooms attached, two disinfecting rooms, a canteen and linen office together with required stairs, ladders and companion hatches.

OFFICERS' AND CREWS' ACCOMMODATIONS

New accommodations for about 350 officers and crew will be constructed and fitted out completely in the spaces from *A* to *G* decks. They will consist of staterooms for officers and petty officers, berthing space for crew, officers' messrooms, pantry, a crew's galley, lavatory and toilet spaces, bathrooms and shower baths and a hospital together with required stairs and ladders.

EXTENSION OF SUPERSTRUCTURE

The midship bridge house structure at *A*, *B* and *C* decks will be extended forward to frame 73½ and *A* deck with its house aft to frame 168. Within this extension a portion of the new passenger and crew accommodations will be arranged. These extensions necessitated the removal of the existing deck house on *D* deck between frames 73 and 98 and also the elimination of two existing cargo hatches between frames 82 and 104 which pass through *D*, *E* and *F* decks and the one cargo hatch between frames 153 and 157 through *B* to *F* decks inclusive.

The existing pilot house and chart house will be removed and replaced with a teak house of slightly larger dimensions.

General Data: Passenger and Cargo Steamship President Buchanan

General Information

Service: North Trans-Atlantic Passenger Service.
Builder: Harland & Wolff, Belfast. Built in 1907.
Owner: U. S. Shipping Board.

Characteristics

Length, overall 615' 3"
Length, B. P. 600' 0"
Breadth, molded 68' 0"
Depth, molded to "D" deck 52' 0"
Draft, loaded 33' 0"
Block coefficient, approx. 0.76
Speed, loaded, knots, normal 13½ knots
Framing, transverse, spaced 30½"
Class American Bureau of Shipping

Tonnages

(In tons of 2,240 pounds)
Displacement at 33' draft 29,250
(In tons of 100 cubic feet)
Gross register when reconditioned 18,400
Net register when reconditioned 13,500

Complement

Deck officers 8
Deck crew 15 petty 36 seamen
Engineer officers, incl. deck engineers 14
Engineer crew 43
Purser's and steward's department 238
Total officers and crew 354
First-class passengers 717
Second-class passengers none
Third-class passengers 1,424
Total passengers 2,141
Total complement 2,495

Life Saving Equipment

Lifeboats	No.	Type	Length

Number 4 D.E. and 2 S.E.
Type Scotch
Length D. E.—19' 0" S. E.—10' 9"
Diameter D. and S.—15' 6"
Fuel Oil
Draft Howden Forced
Total heating surface, square feet 23,503
Total grate surface or furnace volume 567
Superheat, degrees F.
Working pressure, lbs. per sq. in. 215

Engines

Number 2
Type 4-Cyl. Quad. Expansion
Size 25 x 36 x 52½ x 75 x 54
Horsepower 7,500 I. H. P.

Refrigerating Machinery:

Two 15-ton York CO₂ Compressors
Two CO₂ Condensers
Two Evaporators
Brine and Circulating Pumps.

Electric Equipment:

Generators Turbo, 3, 200-kw.
Radio
Emergency Diesel Generator, 1, 50-kw

Bunkers

Compartment	Tons
Total fuel bunker capacity	3,130

Auxiliary Machinery

Condensers, main, surface type, 1,671 tubes each, diameter, ¾ inch, length of tubes, 18 feet... 2
Condenser, auxiliary, to be replaced 1
Air pumps, main, attached to main engines... 2
Bilge pumps, attached to main engines 2
Water service pump, attached to main engine... 1
Sanitary pump, attached to main engine 1

Main circulating pumps 2
Main feed pumps, Weir type, 14 1/16 inches by 9½ inches by 27½ inches, drawing water from common float tank located beside pumps and discharging into feed pipe before passing through feed heater 2
Auxiliary feed pumps, vertical simplex 1
Vertical duplex
(Either pump will handle all requirements)
General service pump, simplex type, size 17½ inches steam end by 11 inches water end by 19 inches stroke 1
Ballast and fire pumps, duplex double acting, 9 1/16 inches by 10 7/32 inches by 14¾ inches 1
Ballast and fire pumps, duplex, 10½ inches by 7½ inches by 12 inches 1
Bilge pump, vertical duplex 1
Auxiliary feed pump, 7 inches by 5 inches by 12 inches 1
Fresh water pumps 4
Main sanitary pump 1
Auxiliary sanitary pump 1
Fuel oil pumps, vertical simplex, 2 inches, each pump room 4
Fuel oil heaters 2
Fuel oil transfer pumps, one in each pump room, 7½ inches by 9 inches by 10 inches 2
Oil burners 30
Evaporator, vertical multi-coil type 1
Distiller, vertical multi-coil type 1
Feed water heater, multi-coil type 1

Deck Machinery

Steering gear, consisting of two compound vertical engines controlled by hydraulic telemotor 1
Anchor windlass, also used for warping 1
Winches 18

Lathes 3
Drill press 1
Drill press, electric portable 1
Emery wheels 2
Hand pump press 1
Electric motor 1

This will make it necessary to move the navigating bridge structure to suit the new house.

REARRANGEMENT OF PILLARS AND GIRDERS AND REMOVAL OF STRUCTURAL BULKHEADS

Where existing pillars, girders or bulkheads interfere with the arrangement of the new accommodations, or with proper access to them, they will be removed and re-located in such a manner as to obviate interference. This means that in several places existing steel bulkheads not fitting in with the new arrangement will be removed but where such bulkheads act as supports for decks, suitable pillars or other structure will be substituted.

NEW WATERTIGHT BULKHEADS

Two new main watertight bulkheads will be installed, one at about frame 77 extending from *G* to *D* decks and the other one at about frame 189 extending from the inner bottom to *D* deck. Where watertight bulkheads are modified or re-located, the decks forming watertight flats in way of them will be reconstructed to maintain the watertightness of the compartments. All watertight bulkheads shall comply with the requirements of the American Bureau of Shipping to withstand a test head of water to *D* deck. As the new watertight bulkhead at frame 189 divides the existing cargo refrigeration compartment on *H* deck into two parts it will be necessary to make changes in the insulation, piping and similar details.

AIR PORTS AND FIXED LIGHTS

All existing air ports and fixed lights below *E* deck within passenger and crew accommodations and storeroom will be removed and replaced with 10-inch clear glass fixed lights fitted with dead covers. Additional ports and lights will be fitted as indicated on the contract plans. At *E* deck the existing 12-inch and 14-inch clear glass air ports will be retained

but all those in the cabin, dining saloon, galley and pantry compartments will be made 14 inches. Laycock frameless lights shall be fitted in the *B* and *C* promenade deck spaces as shown on the plans.

DINING SALOON

The dining saloon will be completely reconstructed and rearranged so that more expeditious service can be provided for the passengers. In this connection, the galley equipment will be improved and modernized in every way, including the installation of an entirely electric cooking apparatus, ranges, etc.

DECK COVERINGS

In general all passenger, officer and crew accommodations and the passenger hospital spaces, with the exception of lavatory and toilet spaces, will be laid with Lit-O-Sil-O flooring; where practicable, however, the existing Lit-O-Sil-O flooring shall be retained and such portions as are damaged will be removed and replaced. The existing wood decking in the original second class dining room will be removed and replaced with Lit-O-Sil-O.

Lavatory and toilet spaces, baths and laundries, crew's hospitals, isolation hospitals and operating room will be laid with vitreous tile, galley and pantry spaces will be laid with quarry tile. The staterooms will be laid with carpets, and rugs will be furnished for the social hall, the writing room and ladies' saloon. A portion of the social hall will be laid with maple flooring for dancing.

ARTIFICIAL VENTILATION AND HEATING SYSTEMS

The entire existing artificial and natural ventilation systems in the passenger, officer and crew accommodations, including supply and exhaust fans and their ducts, will be removed and new systems installed. Electrically-driven supply and exhaust fans will be installed in connection with

UCHANAN

THE RECONDITIONING OF THE STEAMSHIP PRESIDENT BUCHANAN

D DECK

E DECK

General Arrangement Plans of Passenger Steamship President Buchanan: Inboard Profile and Plans of D and E Decks

these new systems in conjunction with thermotanks for the heated air supply systems. The air supply to inside rooms in cabin passengers' staterooms on *B*, *C* and *D* decks and to all cabin passengers' staterooms on *F* and *G* decks and to all officers' and crew's staterooms, berthing spaces and messrooms below *D* deck, galley and pantry spaces below *D* deck will not be artificially heated. The air supply to the cabin class social hall, writing and ladies' saloon, smoking and dining room and to all third class staterooms and dining room, hospital spaces, etc., will be artificially heated. Artificial air exhaust systems will be installed from all toilet and lavatory spaces and bathrooms except from the third class lavatory and toilet spaces in the house on *D* deck aft and from all galley and pantry spaces except the galley in the deck house on *D* deck forward.

CARGO HOLD VENTILATION

Existing natural supply and exhaust ventilators to compartments will be retained but those that are not found in serviceable condition will be replaced. However, cargo spaces now assigned to other purposes will have their ventilators removed and new systems installed.

STEAM HEATING SYSTEM

The existing steam heating system will be removed and a new one with cast iron wall type radiators and copper pipe sill heaters will be installed in the passengers', officers' and crew's accommodations.

STEAM COOKING AND WATER HEATING SYSTEM

The existing steam cooking and water heating system will be removed and a new system installed. This will consist of a steam supply for cooking and water heating in galley, bakery, butcher shop, pantry and messrooms and the hot water heating system in the seamen's, oilers' and firemen's washroom and water heaters in the stewards' slop lockers, laundries, hospital spaces, etc., and a salt water heater which will supply all bathtubs and washers except those in the hospital.

PLUMBING

All existing plumbing fixtures, fittings and piping will be removed and new systems installed. Free standing cast iron enamel tubs supplied with hot and cold salt water will be fitted in all bathrooms with the exception of those in the hospital spaces which will receive a fresh water supply from local heaters. In the third class and crew's spaces nickel plated brass washer heads supplied with cold and hot salt water will be fitted. Practically all cabin passenger staterooms, public lavatory spaces, officers' and petty officers' staterooms will be furnished with cast iron enamel lavatories supplied with cold fresh water and fitted with drains. Similar lavatories will be fitted in the hospital spaces and supplied with fresh hot and cold water.

FRESH AND SALT WATER PIPING SYSTEM

The whole of the existing fresh and salt water piping system will be removed and new systems installed. Features of the new systems will be cold fresh water for washing purposes which will be led to all lavatories in cabin passenger staterooms except those in *G* deck and to cabin and third class public lavatory spaces and to officers' staterooms and to such places as galley and pantry spaces, messrooms, operating room, etc.

Another feature will be running ice water which will be supplied to the cabin and third class pantries, service pantries, officers' and crew's messrooms and to drinking fountains in all third class passenger berthing spaces and to engine and boiler rooms. This ice water system will be operated as follows: New pumps located in the engine room will take

water from the drinking water tanks and force it through two filters and a riser to a brine cooled scuttle butt located under the engine hatch from where it will be distributed by means of a circulating piping system.

FIRE DETECTING AND EXTINGUISHING SYSTEM

Fire detection as well as extinguishing apparatus will be installed to cover all cargo spaces and will be on the Rich system. The whole of the existing fire alarm system will be removed and a new manual operated fire alarm system installed in the cabin and third class passengers' and officers' accommodations, crew's spaces, engine and fireroom and refrigeration spaces. This will be supplemented further with an automatic fire alarm system covering all spaces and compartments.

POWER AND LIGHTING DISTRIBUTION

A complete new system for the distribution of electric power and lighting current will be installed in all parts of the vessel and will include portable lighting fixtures in the cargo spaces. This will necessitate the removal of the whole of the existing power and lighting distribution system.

INTERIOR COMMUNICATION SYSTEM

All of the existing interior communication system, including wiring, fixtures and telephones will be removed and the following new systems installed complete, viz., cabin passengers' annunciator system, cabin smoking room annunciator system, deck officers' annunciator system, engineering officers' annunciator system, stewards' annunciator system, cabin, pantry and galley call bell system, watertight door communicating system, refrigerator door communicating system and siren control system, life buoy release, loud speaking telephone system, inter-telephone (5 station) system, mechanical talking and steering telephone system (reconditioned) helm angle communicating system, wiring for submarine signal system, voice tubes and gyro compass installation.

LIFEBOATS

The vessel will be equipped with new lifeboats and handling gear capable of accommodating 2,670 persons. Two motorboats and 42 lifeboats will be installed and they will be operated by mechanical davits.

CABIN CLASS JOINER WORK

In general each stateroom will have one permanent berth, one sofa berth and one or more Pullman type berths. Wardrobes will be built-in and of laminated hard wood with a mahogany finish. Two fold-up seats of hard wood secured to the bulkhead shall be provided for each stateroom except where there is not sufficient room, in which case two camp stools or one seat and one camp stool will be provided.

GYRO COMPASS

A gyro compass system of the Sperry merchant type and of the latest design will be installed. There will be one master gyro compass, one compass control panel, two alarm indicators, two motor generators, two dynamometers, two storage batteries, one set of dry cell batteries, one steering repeater with reading glass and cover for the wheelhouse, one steering repeater mounted in a waterproof stand at the aft docking bridge, one bulkhead type steering repeater in the captain's stateroom, one continuous course recorder for chart room and two bearing repeaters with pelorus stands for mounting on the bridge wings.

FUEL OIL SYSTEM

Many changes and additions to machinery and piping will be necessary to convert the vessel into an oil burner.

The filling stations will be between frames 119 and 122

General Arrangement of A Deck

General Arrangement of B Deck

on *E* deck and shall be carried through a 10-inch filling main and 8-inch transfer lines alongside of a new pipe tunnel to be constructed through deep tanks between frames 79 and 110. The inboard deep tanks between frames 101 and 110 will be used as settling tanks and will be connected to the fuel service system by high and low pump suction.

OIL FILLING CONNECTIONS

There will be 10-inch flange filling connections with strainer fitted in each filling station with 10-inch pipes led through *E* deck to a suitable height above *F* deck along through side of fidley and down to about 12 inches

for determining the height of oil in service in storage tanks will be fitted.

BOILER ROOM

In the boiler room a new single ended boiler equipped with Howden forced draft system will be installed. This boiler will be located on the port side of the centerline of the vessel abreast of an existing single ended boiler.

ELECTRIC GENERATORS

Three new electric generators are to be fitted each capable of developing 200 kilowatts at 1,000 revolutions per minute

below deck with 10-inch gates connecting pipes terminating in a tee near centerline. From this tee a 10-inch pipe will be led through fidley to connect with transfer lines as specified elsewhere. The 10-inch fuel oil filling line will lead to a point at centerline of ship and just aft of forward boiler room boiler, where it will terminate with a 10-inch gate valve. Below this valve there will be fitted a cross fitting with 5-inch branches to each settling tank. Eight-inch transfer lines will lead up each side of pipe tunnel with suitable manifold for filling and emptying individual tanks. These lines will be cross connected after last manifold with a gate valve and cross over pipe.

BALLAST SYSTEM

The ballast system is to be changed so as to provide means for filling or pumping out all double bottoms, fore and after peaks and deep tanks abreast the thrust recess used for carriage of washing water. The present cast iron and steel ballast line will be utilized wherever possible but any defective material is to be removed.

REFRIGERATING MACHINERY

Two 15-ton York CO₂ compressors driven by single vertical engines will be installed to replace present machinery which will be removed along with its evaporator. There will also be two CO₂ condensers fitted and each will be of sufficient capacity to accommodate one machine when operating at its maximum capacity.

TANK GAGING, SOUNDING AND SIGNALING SYSTEMS

The conversion of double bottoms to oil tanks will require the installation of sounding pipes in every tank and pneumaticators or some other method

They are to be driven by geared turbines operating at 5,000 revolutions per minute. Turbine and generator will be mounted on a common bedplate.

These turbines are to be capable of operating under a boiler pressure of 215 pounds per square inch when exhausting against a back pressure of 15 pounds above atmosphere. With normal steam pressure of 200 pounds per square inch and a back pressure of 10 pounds per square inch at the stage the requirements for steam consumption for half and full loads will be as follows: At full capacity, 52 pounds and at half capacity, 62 pounds.

The deep tanks and settling tanks will have a capacity of about 3,130 tons of fuel oil. Fourteen tanks, including the two settling tanks, will be constructed forward of the boiler

room, extending from frame 79 to frame 111 and from top of double bottom to *G* deck. This will involve the construction of two new oiltight bulkheads and an oiltight pipe tunnel on the double bottom at the centerline.

MACHINERY ALTERATIONS

The main and auxiliary propelling machinery and boilers will be given a complete overhauling and the term "overhauling" means that every item in the engine department will be given a thorough examination and all defective parts will either be reconditioned or renewed. The main engines, which consist of two vertical inverted quadruple expansion engines, will be given very careful attention and placed in first class operating condition.

Propellers—II

Factors Which a Propeller Formula Should Contain— Application of Froude's Formula to Full Size Propellers

By Alfred J. C. Robertson*

IN the preceding article the writer has shown how propeller data such as are given in Taylor's paper on "Propeller Position" (MARINE ENGINEERING AND SHIPPING AGE, December, 1922) can be used for the calculation of wake and thrust deduction from trial trip results and also how such data may be utilized for design purposes. Unfortunately, however, there is still very little of such propeller data available and it will therefore be interesting to see whether formulae such as Froude has used for his propellers will be of assistance to us.

But before trying to express the work of a propeller mathematically it will be necessary to refer to the various elements of a propeller as regards their effect upon the absorption or giving out of work.

PITCH RATIO

By far the most important element is the pitch ratio, the ratio of pitch to diameter. Assuming fixed diameter and revolutions, and speed of advance, there is always a pitch ratio at which the propeller does no work. A propeller of less than this pitch would tend to reduce the speed of advance, i. e. would absorb thrust instead of giving it out. As the pitch is increased the slip ratio increases and thrust also increases with a somewhat lesser increase of torque until maximum efficiency is reached and thereafter the rate of increase of torque is somewhat greater than that of thrust representing a continuous increase of horsepower but a decrease of efficiency.

The slip at no thrust is usually termed the effective slip and the corresponding pitch is equal to the speed of advance in feet divided by revolutions. This effective pitch is nearly always greater than the face pitch of the screw.

In Taylor's propeller No. 570 there is a condition of no thrust at—.07 percent slip, i. e. face pitch is 93 percent of effective pitch. For propeller No. 569 the effective slip is

$$\frac{1}{.91} \text{ of face slip, and for No. 571 the ratio is } \frac{1}{.88}.$$

It is evident therefore that the thrust developed is dependent upon the effective pitch ratio in conjunction with the effective slip ratio, and highest efficiency is reached at

about 21 percent effective slip for a pitch ratio of 1.5 and about 26 percent for a pitch ratio of .8 the slip for highest efficiency increasing with decrease of pitch.

BLADE AREA

The next propeller element of importance is the blade area, either developed or projected, and with area we must consider its distribution in two, three or four blades; and the shape of the blades, whether elliptical or wide tip. We must also consider the size of the propeller boss which naturally affects the shape and area of the propeller blades.

For comparative purposes it is necessary to express blade area by a ratio of the diameter, as mean width, or of $0.785 \times \text{diameter squared}$ as a ratio of the propeller disk.

It should be noted that area is important in the development of thrust, but that thrust does not increase nearly as fast as increase in propeller area, and efficiency generally decreases as the area ratio increases.

The same principle apparently applies in reference to the number of blades, but to a less extent—there is a small sacrifice in smooth water efficiency by increasing the number of blades in excess of two, but the difference is small and is generally more than offset by the more even torque, and there is a distinct advantage as regards stress conditions in the material of the blade, where three or four blades are used instead of two.

PROPELLER BOSS EFFECT

The propeller boss effect has never been accurately measured but as it affects the stream line motion through the propeller disk as well as the shape and center of effort of the propeller blade it is necessary to take some account of it. In general, Taylor's propeller bosses have a diameter of 20 percent of the propeller diameter and, if this rule is adhered to, comparative bossing effects will be eliminated.

Regarding the outline of the blade, many claims have been made for particular shapes, but no shape has been proved more efficient than a true ellipse and this shape is probably as strong as any so that there is no reason to depart from it.

The remaining propeller element having any important bearing on its thrust or efficiency is the blade thickness.

*Naval architect, Munson Steamship Line, New York.

This is best expressed for comparative purposes as the axial thickness.

The blade face and back are usually straight lines extending from the propeller centerline to its circumference at somewhat different angles and meeting at the blade tip. The distance on the fore and aft centerline of the propeller which separates these two lines is termed the axial thickness and is expressed as a ratio of the diameter. This axial thickness is a necessary evil, but may be reduced as the mean width of the propeller is increased and in Mr. Taylor's data this is done. Mr. Froude adhered to the same axial thickness throughout his experiments.

PROPELLER FORMULÆ

Any propeller formula should therefore contain, in addition to diameter, revolutions and speed of advance, factors

Taylor's Propeller No. 571

expressing the blade area and shape, the pitch ratio and the slip ratio.

Froude's propeller formula is:

$$\text{Thrust Horsepower} = Va^3 \times D^2 \times B \times \frac{(p+21)}{p} \times \frac{S}{310.9} \times \frac{(1-.08S)}{(1-S)^2}$$

where Va is speed of advance of propeller in knots, D is diameter in feet, B is a blade factor depending on the number of blades, their area and their shape, p is analysis pitch ratio, and S is analysis slip ratio. It will be noticed that the above formula does not include any adjustment of power due to variation of boss diameter or axial thickness. The former is partially covered by disk area ratio on which B values are plotted and the axial thickness is important

chiefly as it affects true (analysis) pitch, but there is room for further study along both these lines.

For application to full size propellers, Froude concluded that analysis pitch should be assumed as two percent higher than face pitch, and this is the particular feature of Froude's data which causes doubt and confusion.

In examining a number of propeller data curves, the writer has concluded that the slip correction factor $(1 - .08S)$ could well be modified to $(1 - S/3)$ and with this correction C_T may be written:

$$C_T = \frac{B}{2.723} \times \frac{p+21}{p} \times S(1-S/3) \times \left(\frac{\text{Analysis Pitch}}{\text{Face Pitch}} \right)^2$$

$$\text{and } T.H.P. = \frac{C_T \times R^2 P^2 D^2 V}{117.24}$$

where R = Revolutions in hundreds.

P = Face pitch in feet.

D = Diameter in feet.

the constants 2.723 and 117.24 being simply dimension correction factors.

A curve of C_T is shown herewith plotted by formula, together with Taylor's experimental C_T for propeller No. 571, and it will be noted that the C_T curves would coincide if "B" value were taken at .1084 instead of .1066. Such a difference would easily be accounted for if corrections for diameter of boss and axial thickness were included in the formula*.

A very convenient way of plotting propeller data is a modification of Taylor's ρ^{δ} diagram suggested by a study of Froude's formulæ.

$$\text{On a base of Taylor's } \rho = \text{Revs.} \sqrt{\frac{Q.H.P.}{Va^5}}$$

or, more conveniently for use where the effective horsepower

$$\text{is known from tank tests, on Revs.} \sqrt{\frac{T.H.P.}{Va^5}} \text{ curves of } \frac{D \times R}{Va}$$

may be plotted for each pitch ratio, with corresponding efficiency and slip ratio curves, so that it is possible by inspection at once to select the best diameter for any particular problem and its corresponding pitch ratio; and the slip ratio may also be read off, this factor being necessary for the analysis of trial results.

Where the effective or analysis pitch is unknown, face pitch can be used as Taylor has done. It is, however, interesting to note that curves of C_Q and C_T may be plotted by formula on face slip ratio, the formula of course having adjusted blade coefficients and including the addition of C_Q and C_T values at zero slip ratio, these quantities being expressed by a formula which includes the various blade elements.

There is quite a discrepancy as a rule between the results of a ship on the measured mile and the results reported in the ship's log and until the discrepancies between these two sources of data are satisfactorily explained it is difficult to make any material advance in our knowledge of propeller performances.

There is no doubt that the average weather at sea adds to the resistance of a ship over that experienced in smooth waters on the measured mile, but there is also no doubt that the I. H. P. reported at sea, or even the S. H. P. by the torsion meter, give far from satisfactory results and can hardly be relied upon within five percent, even when carried out with care. But, in many cases the engineers, seeking to get all the credit they may in fuel economy, will take indicator readings at the maximum power in a day's run. This gives us a low figure for the fuel consumption but gives us

(Continued on page 239)

*Froude's boss diameter was 9 percent of diameter; Taylor's is 20 percent. Froude's axial thickness was 3 percent of diameter; Taylor's is 4 percent.

Recent Motorship Building In Europe

**Large Number of New Motorships and Motor Liners
Now Under Construction and in Contemplation**

By Our Special London Correspondent

PARTLY because of the increasing confidence which is now felt in the marine internal combustion engine, and partly because of the shipowner's undoubted preference for single screw motorships, there is now a marked tendency in Europe to build vessels of this class. Orders have recently been placed for nine or 10 motorships totaling about 60,000 tons deadweight, the installation in each case comprising a single Doxford opposed piston engine of 2,000 or 3,000 brake horsepower. The Holt Line is having a 10,000-ton vessel constructed in which will be fitted a 3,000 brake horsepower six-cylinder Camellaird Fullagar engine, running at 85 revolutions per minute, this being the largest of its type yet produced, while Messrs. Fearnley and Eger of Christiania, have ordered two 7,500-ton single screw ships, each equipped with a 2,600 brake horsepower motor.

In single screw vessels, relatively low speed of rotation is, of course, essential for high propeller efficiency and all of the engines used for the purpose are of what is termed the long-stroke design with a high stroke-bore ratio, the speed

varying between about 75 and 85 revolutions per minute. It might be thought that in this connection, the two stroke type would show to special advantage, particularly in the higher powers. This is undoubtedly the case, but builders of the four-cycle Diesel engine have tackled the problem energetically, with the result that long-stroke, slow-speed motors of this design, are now being constructed in powers up to 3,000 indicated horsepower.

NEW BURMEISTER AND WAIN ENGINE

The first example of such an engine has just been completed by Burmeister and Wain, and is now being installed in an 8,000-ton cargo vessel, under construction at Palmers' Yard on the Tyne, for the Ocean Steamship Company, of Liverpool. Its full output of 3,000 indicated horsepower is developed at 85 revolutions per minute and as will be seen from the illustration, it is an eight-cylinder type with a single three-stage air compressor. This is a point of some interest since in the 3,000 indicated horsepower Burmeister

The First 3,000 Indicated Horsepower Burmeister and Wain Long Stroke Engine for a Single Screw Ship

and Wain engine used in twin screw ships (running at 115 revolutions per minute), two air compressors in tandem have invariably been provided. Equally noteworthy is the fact that in the ship in question, there is to be no electrically driven auxiliary compressor for the supply of air for starting and maneuvering purposes. It is considered that the surplus air from the compressor on the propelling engine and the individual three-stage compressors on the Diesel engines driving the electric generators, will be sufficient for all purposes.

The engine has cylinders 29.13 inches in diameter and a 59.06-inch stroke, the bore being the same as that of the short stroke engine of the same power, while the stroke is 13.78

the starting platform and by means of a system of levers and a lay shaft, the lift of all the fuel valve spindles is regulated at the same time. On the test bed it was found that in this way the speed of the engine could easily be controlled down to about 20 revolutions per minute. So far as the method of valve operation and reversing are concerned, no alteration has been made from normal practice. The first of these engines built by Harland and Wolff has been installed in a 6,500-ton vessel built in Spain for the Sota y Aznar Company, while the second is for a 7,800-ton cargo ship for Messrs. MacIver and Company, Liverpool.

A 15,000-TON MOTOR LINER

If as is generally believed, the type of passenger liner most commonly built in the future is one not exceeding 20,000 tons displacement, it is probable that a majority of these vessels will be equipped with internal combustion engines since motors are now available, suitable for the propulsion of such craft. In addition to the 22,000-ton, 18-knot passenger liner for the Union Steamship Company of New Zealand, which the Fairfield Company is now building on the Clyde, an order has just been placed for a vessel of 15,000 tons by the Rotterdam Lloyd Steamship Company for service between Rotterdam and the Dutch East Indies. Two further contracts are likely to be fixed in the future, one for a transatlantic liner for the Scandinavian American Line in which machinery of about 15,000 brake horsepower is to be fitted, and the other a liner for the United Steamship Company with twin screw machinery of 14,000 brake horsepower. In this latter ship it is stated that two double acting four-cycle engines of a new type will be installed.

LARGEST INSTALLATION YET CONSTRUCTED

The new liner for the Rotterdam Lloyd Steamship Company, which is being built at the De Schelde Shipbuilding & Engineering Company's yard at Flushing, will be 500 feet long and will have a draft of 27 feet. The propelling machinery will comprise two Sulzer two-cycle engines each of 3,500 brake horsepower with six cylinders, and the notably low speed of 85 revolutions per minute

will be adopted. The two motors will be the largest that have yet been constructed for installation in a ship, and it is a matter of interest that they are to be built under license by the Dutch firm which has not hitherto engaged upon the manufacture of marine Diesel engines.

TURBO BLOWERS WILL SUPPLY SCAVENGING AIR

The motors will be of the standard Sulzer type with auxiliary port scavenging and the new system of providing scavenging air by means of separately driven turbo blowers will be utilized, instead of having piston scavenging pumps driven off the engine crankshaft. There will probably be three of these blowers, each driven by a direct current motor of about 200 brake horsepower and two sets will be in operation when the vessel is at sea. This will naturally involve very large electric generating equipment, and Diesel engines totalling 1,500 brake horsepower will be fitted, driving the generators. The liner will carry about 400 passengers at a speed of 15 knots, in addition to a certain amount of cargo. All the auxiliary plant will be electrically operated, including winches, steering gear and engine room pumps. It is understood that the new ship will be completed about the same time as the liner for the Union Steamship Company, namely, towards the end of the summer of 1924.

1,800 Brake Horsepower Long Stroke Diesel Engine Built by Harland and Wolff

inches greater. There is, however, little difference in the piston speed, which in this motor, is about 820 feet per minute. This is a figure which experience has shown, may well be exceeded and the builders are already prepared to construct eight-cylinder engines on the same principle developing 4,000 indicated horsepower. Incidentally it may be stated that the mechanical efficiency is in the neighborhood of 80 percent and the shaft horsepower developed by the engine illustrated is slightly under 2,400.

NO VARIATION IN GENERAL DESIGN

There is no variation in the general design of the long-stroke engine in comparison with the normal type, apart from the minor modification in construction necessitated by the long-stroke, and the adoption of a single, instead of two compressors. Harland and Wolff, the British licensees of Burmeister and Wain, have just completed two engines of the same type but with six cylinders, the output in this case being 1,800 brake horsepower at 85 revolutions per minute. In order to obtain increased flexibility of operation, an arrangement has been devised whereby at low speed, the lift of each of the fuel valves in the six cylinders may be diminished.

This operation is carried out by turning a handwheel at

Dyson's Method Applied to Merchant Ship Propellers*

By E. A. Stevens, Jr.

During the transactions of this society in 1920, Admiral C. W. Dyson presented a paper entitled "The Problem of the Hull and Its Screw Propeller," in which a number of examples were shown. These were all navy vessels with the exception of the first problem. It has been claimed by many that, while this method is very accurate for these vessels, especially those fitted with twin screws, the block coefficients of which do not exceed 0.65, it might not be applicable to merchant ships with full lines and fitted with one propeller. The writer presents in this article several ships of this type, together with other types of merchant ships, and shows the results of Dyson's analysis, together with the results obtained on the trial trips.

AN argument used against Dyson's method is that while the anticipated power and revolutions obtained by the calculation compare favorably with those developed on the trial trip, the same cannot be said regarding the power and revolutions per minute obtained at sea. This, however true it may be, is not due to the method but to the way it is used. In the latter case, an addition of 20 to 30 percent should be made to the effective horsepower of the ship as found from the model test.

Before attacking any of the problems it might be well to mention one thing. The basic slip (S) is dependent not only on the corrected block coefficient but also on the ratio of twice the length of after body divided by the draft. In a few cases coming to the writer's attention, it was impossible to obtain the length of after body. In order to make a reasonable estimate of this length, about forty-five ships were plotted with block coefficients as abscissas and length of after body divided by length between perpendiculars as ordinates. These varied considerably, but a fair average would be as shown in the following table:

L. A. B.		L. A. B.	
B. C.	L. B. P.	B. C.	L. B. P.
0.60	0.50	0.725	0.407
0.625	0.494	0.750	0.376
0.65	0.48	0.775	0.339
0.675	0.46	0.80	0.302
0.700	0.436	0.825	0.265

If the ship is fitted with a cruiser stern, the length of waterline should be used in place of length between perpendiculars.

If the above table is used for obtaining the length of after body, quite accurate results will be obtained as, in the majority of cases, it requires a material change in the basic slip to appreciably affect the revolutions.

The various problems may be divided into three groups: (1) Single-screw vessels; (2) vessels fitted with two or more screws, the wing screws being carried in struts; (3) vessels fitted with two or more screws, the wing screws being carried in bosses or spectacle frames.

GROUP 1

Problem 1.—The ship used in this problem is the S. S. *Gulfprince*, the trials of which were described by Mr. H. A. Everett in his paper entitled "Power and Speed Trials of Ten Thousand Deadweight-Ton Tanker," which was published in last year's volume of the transactions of this society. It will be noticed that the actual power is less than that calculated at the higher speeds, while at the lower speeds the reverse is the case. As the after body is quite long, the value of K is probably less than that shown on the chart, while the increase in actual power of the lower speeds in relation to that calculated is undoubtedly due to the falling off of the mechanical efficiency of the engine at the lower powers.

*Paper read before the Society of Naval Architects and Marine Engineers, New York, November 8, 1922.

Problem 2.—As this model had never been tested in the tank, no effective horsepower curves were available. The revolutions estimated (by using the indicated horsepower developed on the trial) compare favorably with those obtained on the trial. Calculations were then made for the effective horsepower which also compare favorably with an estimated effective horsepower obtained by using Taylor's

method. The resistance per ton of displacement was taken from a ship of the following dimensions: Length between perpendiculars, 380; beam, 53; draft, 24; displacement, 10,900 tons; block coefficient, 0.79; midship section coefficient, 0.988.

Problem 3.—This ship was fitted with geared turbines. Unfortunately, no torsion meter was installed, but the shaft horsepower was estimated from curves supplied by the manufacturer of the turbine. The vessel was first run on a twelve-hour trial, during which the following were the average pressures and temperatures:

Pressure at throttle	186 pounds gage
Pressure at nozzles	182 pounds gage
Superheat	Not given
Temperature at exhaust	96.3 degrees F.
Vacuum corresponding to 96.3 degrees F.	28.3
Shaft horsepower from curves	2,500

Progressive runs were then made over the Provincetown course with the following results:

Speed in knots	Revolutions per minute
6.355	50.075
8.055	64.05
9.511	74.00
11.447	89.37

From this the speed on the twelve-hour run was estimated to be 11.38 knots.

It will be noticed that while the revolutions per minute on the trial practically agree with the analysis, there is quite some difference in the horsepower. This might be explained

acy of the gages and thermometer or a difference between the superheat obtained on this trial and that for which the curves were drawn.

Problem 4.—As there was no measured mile within reasonable distance, the run was made from Ambrose Light Ship to Fire Island Light Ship and return. The revolutions were held as near constant as was possible, and indi-

cator cards were taken every fifteen minutes. While the results are not as accurate as if the run had been made over a measured mile, it is believed they are sufficiently accurate to warrant presenting them in this paper. There was a very slight swell and a breeze of not over 3 knots during the trial.

Problem 5.—The data for this problem were taken from "Notes on the Performance of S. S. Tyler," by Mr. E. H. Rigg, published in Vol. XX of the transactions of this society. The data given as actual indicated horsepower and R_d are those observed on the trial runs. If those of the faired curves had been given, the actual indicated horsepower for 12.233 knots would have been 1,480 and the actual R_d would have been 90.8 and for 9.876 knots the actual indicated horsepower and R_d would have been 790 and 73.2.

Problem 6.—The power and revolutions as given by an analysis did not agree with those obtained on the trial. As the difference was so great, an investigation was made as to the causes. It was found that the wheel was working in cavitation and the effective horsepowers were greater than those shown on the curves. An analysis was made for revolutions (using the indicated horsepower from the trials), which check with those obtained on the runs. The effective horsepowers were then calculated and compared with those of Model 1013, the block and midship section coefficient and dimensions of which are the same as this ship. The length of after body was the same, while the middle body of Model 1013 was slightly less and the fore body slightly longer. The forward sections of the ship were more of the U shape, and the after sections had more of a club foot than the model. According to experiments conducted by Professors H. C. Sadler and E. M. Bragg, the results of which were published in last year's transactions, it would appear that Model 1013 would require slightly less power for these low speeds. This would only partly account for the difference; the remainder would probably be caused by the condition of the ship's bottom. The vessel was drydocked and then loaded, after which the trial was run. The time between drydocking and the trial was about three weeks.

Problem 7.—The results of the trials at two speeds of three ships of the same design, together with the analysis, are given in this problem. No effective horsepower curves were available. The revolutions were calculated using the indicated horsepower. The effective horsepower was then calculated and compared with that estimated.

GROUP 2

We will now pass to the second group; namely, ships fitted with more than one screw, the shafts of the wing propellers being carried in struts. The first two, Problems 8 and 9, are the navy colliers *Jupiter* and *Cyclops*. While these are not merchant ships, their forms are very similar to moderate speed freighters or to slow speed passenger and cargo ships and are included in this paper for lack of other available data.

Problem 8.—As the writer was not in possession of the length of after body of this ship, an estimate was made using that of the *Cyclops* (Problem 9).

Problem 10.—This ship had been in the water for some time before the trial, which accounts for the difference in horsepower between the estimate and that obtained on the trial. Unfortunately indicator cards were not taken on the mile run, but were taken after the same. The average power was 6,155 and average revolutions 102.75. Assuming the power to vary as the cube of the revolutions we have

$$6,155 \times \left(\frac{104.75}{102.75} \right)^3 = 6,540, \text{ which is used as the indi-}$$

cated horsepower on the mile course. If this figure (6,540) was used in the calculations for slip in place of the estimated power, R_d would have been 102.8 in place of 101.8.

tested at three drafts with model propellers. While the powers check very closely in all three cases, the estimated revolutions at 36-foot draft do not agree with those obtained from the model test. As this draft (36 feet) is four times the height of the center of propeller above the base line, this might be considered as a deep-draft vessel with propellers carried as deeply as possible, which condition is not covered in Admiral Dyson's latest work. A correction should be made for obtaining the basic slip. The writer is not prepared to say just how this should be made, but two ways are possible; first, taking the slip block coefficient and basic slip at a lighter draft, or second, by using a line on the block coefficient chart passing through the lower left-hand corner of the chart and cutting the right-hand side somewhere above line X. The slip block coefficient would then be less and the basic slip greater than what it would be by using line X.

A trial was run on a ship similar to this but fitted with different propellers. It will be noticed that, while the revolutions agree, there is some difference in the power. This was caused by the run being made on the Delaware Breakwater Course. The lack of deep water affects the power but does not seem to vary the revolutions for given speeds. This was shown by tests conducted by the United States Navy on the battleship *Michigan*, which was run over the Rock-land, Provincetown and Delaware Breakwater courses. While the revolutions for various speeds were practically the same on all the courses, the power varied considerably. As the draft and range of speed of the two ships are practically the same, it would be safe to consider that, had this ship been tested in deep water, the power developed would have been very close to that estimated, while the revolutions would be the same as those obtained on this trial.

The propeller shafts of both model and ship were carried in bosses set at about 32 degrees with the horizontal plane, the intersection of which with the hull was probably parallel or nearly parallel with the stream lines.

Problem 12.—The angle between the bosses and the horizontal plane on this ship was about 10 to 15 degrees which, as will be seen in the calculation, seems to affect the basic slip. The revolutions were first calculated using the value or slip block coefficient as given on line X, then using line Y.

In the former case the calculated revolutions were greater and in the latter they were less than those obtained on the trial. By using a value between these two, the calculated R_d worked out almost the same as the actual R_d . On account of lack of data, the value of K cannot be determined, but an estimate was made of the effective horsepower by the Taylor method and by calculation from the propeller data. There was quite some difference between these, which would be accounted for if the draft during the trial (which is not known) was less than 29 feet.

Problem 13.—For the same reason as mentioned in Problem 4, this ship was run from Ambrose Light Ship to Fire Island Light Ship and return. Unfortunately, the only effective horsepower curve available was for a draft of 28 feet 2 inches. Assuming the effective horsepower to vary as a means of the ratios of the displacements and the displacements to the two-third power, we have:

Displacement at 28 feet 2 inches	16,900
Displacement at 24 feet 0 inches	14,250
$(14,250 \div 16,900)^{2/3}$	0.894
$14,250 \div 16,900$	.844
Mean	.869
Effective horsepower (28-foot 2-inch draft) at 11.64 knots	= 1,860
Effective horsepower (24-foot draft) at 11.64 knots	= $1,860 \times 0.869 = 1,615$.

The above powers included the resistance of the rudder and bilge keels but not the propeller bosses, which is estimated at 80, making a total effective horsepower of 1,695. This vessel was fitted with Diesel engines, the mechanical efficiency of which was about 75 percent.

The angle of the bosses with the horizontal plane was about 20 degrees.

Problem 14.—This ship is the *Great Northern*, the trial-trip data of which were published in the *Journal of the American Society of Naval Engineers*. The values of effective horsepower, which were obtained by multiplying the shaft horsepower by the propulsive coefficients as shown on the trial curves, are probably that for the bare hull, as the propulsive coefficients are quite low and as the propellers are apparently out of cavitation. The revolutions were calculated using the shaft horsepower from the trial data, and compared with the actual revolutions. Calculations were

then made for the effective horsepower. The difference between the calculated effective horsepower and those obtained by multiplying the shaft horsepower by the propulsive coefficients could be taken as the power required for the appendages.

CONCLUSION

In the foregoing are represented almost every type of seagoing merchant ships. Problems 1 to 7 are single screw ships and, with the exception of Problem 5, have full lines, the block coefficients being over 0.77. Problem 13 is a full-bodied cargo ship with twin screws. Problems 8, 9 and 10 are of the slow cargo and passenger type or moderate speed freighter, fitted with twin screws. Problem 11 is a moderate speed cargo and passenger ship, while Problems 12 and 14 represent high speed passenger vessels. The vessel in Problem 5 was built for the coast trade between New York and Norfolk. When loaded to her deep draft (about 22 feet) her underwater body was similar to a moderate speed cargo and passenger vessel with single screw. At the draft at which the trial was run (16 feet 11 inches), the underwater body was more like a sound or river steamer with a full midship section.

The writer regrets that he had to include in this paper examples where either very accurate or full information was not obtainable, but was obliged to do so because of the lack of more complete data.

Flexible Couplings Make Direct Motor Drive Compressors Possible

BECAUSE of the demand for a small air compressor which could be directly connected to an electric motor, the Chicago Pneumatic Tool Company, Chicago, Ill., has recently developed a line of high speed compressors which can be directly connected to either electric motors or internal combustion engines by means of flexible couplings. The compressors are of the vertical, duplex, single acting, water-cooled type fitted with "Simplate" flat disk inlet and discharge valves. The straight and uniform lift of these valves affords a maximum effective valve area which makes possible the speed at which these compressors operate.

Small Air Compressor Directly Coupled to Electric Motor Through Flexible Coupling

The machines are built in three sizes having piston displacements of 128, 160 and 210 cubic feet of air per minute and are suitable for working pressures of 150 pounds per square inch. The standard speed of these sizes is 600 revolutions per minute.

The equipment includes a hand starter for the motor and an inlet valve unloader for the compressor. Where the demand for air is intermittent the motor can be furnished with an automatic starter which starts and stops the unit within pre-determined pressure limits. When this type of starter is used the compressor is equipped with a centrifugal unloader which automatically relieves the compressor of its load while the motor is starting up or shutting down. A water control valve is also furnished which is operated by air pressure governed by a centrifugal unloader. Since the lubrication is accomplished by a combination pump and splash system the entire unit is automatic as the electric current, air delivery, circulating water and lubrication are all accurately controlled automatically.

NEW ITALIAN LINER.—The Navigazione Generale Italiana announces that they have now in the course of construction a new passenger vessel, the *Duilio* which is to be a sister ship of the *Giulio Cesare*, of 21,500 tons.

Uncle Sam's Lightships No Longer Out of Touch with the World

Uncle Sam has now equipped his lightships with the very latest and most modern radio equipment. The lightships can transmit and hold conversations with incoming ships to determine their positions at sea, also broadcasting fog and danger signals. The loneliness of the personnel of the lightships is now solved by the latest radio equipment which is installed under the direction of the Lighthouse Service in Washington which will enable the lightship keeper to tune in on concerts, lectures, etc. The above photograph shows the radio compass of the lightship at Ambrose Channel with first officer George H. Peterson seen tuning in. Note the receiving set on the right which consists of detector and six stages of audio frequency amplification.

The Current Actuated or Flettner Rudder*

Every rudder in a certain sense is current actuated since rudder pressure is only developed by a current. The new rudder described in this article also derives from the current the forces necessary for setting the rudder itself, constituting a fundamental departure from the time-honored arrangement of ships' rudders. The forces required for holding the rudder of a large ship against the current are very great, necessitating powerful steering engines to develop the turning moment necessary to rotate the rudder stock. By using the current actuated rudder the necessity for such great forces may be avoided and large ships may be steered by hand.

THE first practical application on a ship of the Flettner or current actuated rudder was made on the steamship *Frigido*, following several years of investigation with models and after a series of trials had been conducted upon a motorship. This experimental motorship was fitted with a current actuated rudder early in 1920 in order to test the practicability of the device, particularly in going astern. The scheme of using an auxiliary rudder at the after end of the main rudder for the purpose of developing side pressures for setting the main rudder was first applied in large German battle planes, several hundred of which were fitted with this appliance.

Before going into the details of the rudder, a few remarks are necessary to point out the elementary principles upon which the rudder depends.

PRINCIPLES AFFECTING RUDDER ACTION

Let us assume a ship in which a standpipe is fitted in connection with the water outside through a small pipe (Fig. 1).

With the ship in motion, the water in the standpipe sinks to a new level depending upon the velocity. This principle has been used in a well known type of speed measuring device.

As another example, Fig. 2 shows a canal in which the water is motionless. As soon as the water is put in motion, the

level in the standpipe (Fig. 3) drops. The height of water remaining in the tube (p) indicates the pressure existing in the stream at the orifice of the tube. The difference between the level in the tube and the level outside represents the loss in potential energy and the gain in kinetic energy in the moving liquid. This difference in level is a measure of

Fig. 1

Fig. 2

Fig. 3

the kinetic energy in the liquid and where the velocity is v , the kinetic energy equals $\frac{v^2}{2g}$ (for metric units). If the loss in pressure is known, the velocity of the stream may be calculated.

If we explore the surfaces of a rudder which is set at an

angle to the current and plot the pressures we will obtain a diagram similar to Fig. 4, where we find upon the one side

Fig. 4

Fig. 5

of the rudder a loss in pressure and upon the other side a gain in pressure. Furthermore, this loss or gain is not uniform over the length of the rudder but in general is greatest

Fig. 6

near the leading edge. As a consequence of the unequal distribution of the pressure, the center of pressure is near the leading edge for small angles. For an angle of 90 degrees

*Abridged translation by Lieutenant E. L. Gayhart, C. C., U. S. N., of an article by Anton Flettner, Director of the Flettner Schiffsverf-Maatschappij Rotterdam-Berlin, appearing in *Werft-Reederei-Hafen* of August 22, 1922.

to the current the center of pressure moves to the center of the area, and for intermediate angles the motion is about as indicated in Fig. 5.

CURRENT ACTUATED RUDDER

The principle underlying the current actuated rudder is the development of a difference in pressure at the after edge of the rudder, which difference in pressure shall have a determined direction. Fig. 6 is a schematic representation of the new rudder arranged as an underhung rudder, while Fig. 7 represents the form as installed on the *Frigido*.

Figs. 8 and 9 represent diagrammatically the plan view of the rudder when going respectively ahead and astern. In

Fig. 7

these views, the positive and negative signs represent excess and diminished pressure and the number and distribution of these signs show the relative values of these pressures. When, as here shown, the auxiliary rudder is turned, a reduction in pressure occurs at the convex side of the angle in the vicinity of the auxiliary rudder with a feeble increase in pressure on the opposite side. If the auxiliary rudder had not been turned, the location of the center of pressure somewhat abaft the axis would have resulted in bringing the main rudder back to the midships position. But with the auxiliary rudder set as shown in the diagram, a certain pressure difference is developed at the after edge of the main rudder and the combined center of pressure of the system moves to the axis. The rudder then hangs in equilibrium as shown.

Mathematically, we might consider the system as a lever where the force P acting on the arm x is balanced by the force $P/20$ acting on an arm $20x$. This ratio of 1:20 is

assumed for example; actually, it may be made even more favorable by appropriate design.

Fig. 10 represents a ship with rudder of ordinary type at the moment of meeting the ship with the rudder when

Fig. 8

straightening out from a turn. The current momentarily strikes the rudder at an angle of between 80 and 90 degrees. The center of pressure is near the middle of the rudder and, in consequence, the forces acting on the rudder are ex-

Fig. 9

cessive and the position of the rudder to the current is unfavorable for developing a turning effect on the ship.

The current actuated rudder can never be placed in such an unfavorable position relative to the current since it adjusts itself with respect to the effective direction of the current,

Fig. 10

Fig. 11

Fig. 12

which, in the situation just mentioned, does not correspond with the ship's head. When the helmsman puts his wheel hard over to check the ship's head, the current actuated rudder will not take that actual position but rather will hang momentarily near the fore and aft direction as indicated in Fig. 11. In this apparently unfavorable position the current strikes the rudder at a much better angle for developing turn-

ing effect on the ship than is the case with the normal rudder when put hard over too soon. Experience has demonstrated that the turning of the ship from one direction to another takes place with surprising rapidity.

CONTROL MECHANISM

The control mechanism for this rudder may be represented by the arrangement shown in Fig. 12. Here, *a* represents the main rudder, *b* the auxiliary rudder, and *c* a pulley capable of rotation about the axis of *a*. Suppose that *c* is turned through 15 degrees. Then the auxiliary rudder will be turned in such a direction that its effect on the main rudder will be to cause the latter to follow the motion of *c*. But as the main rudder swings to follow *c*, the auxiliary rudder is turned back toward the neutral position. This arrangement is but another example of the familiar follow-up gear. The main rudder, because of the restoring of the position of the auxiliary rudder by the follow-up action, will not move as far as *c* is displaced but will reach a point where there is equilibrium between the forces on the two rudders.

Now suppose that the pulley *c* is held while the main rudder is forcibly displaced. The action of the mechanism is such as to swing the auxiliary rudder in the same direction and with greater velocity. The effect is shown by the dotted line in Fig. 12. It will be seen that the auxiliary rudder acts to oppose any undesired disturbance of the main rudder, and furnishes an automatic control over the position of the main rudder.

The actual mechanism used for operating the rudder is shown in Figs. 13 and 14. This system of gearing replaces

Fig. 13

Fig. 14

the simple arrangement shown in Fig. 12. The operation of the rudder from the bridge is effected by hand, even with large ships. A cable leads from the steering wheel on the bridge to the so-called upper box which contains a worm and worm wheel. The gear wheel *a* is the main direction element and corresponds to the pulley *c* of Fig. 12. If this gear is turned, it acts to turn the operating shaft of the auxiliary rudder through the arrangement of gears and levers shown. The main gear box is attached to the main rudder stock. The operating shaft for the auxiliary rudder extends down through the hollow main rudder stock and connects to the auxiliary rudder by yokes and parallel rods.

The events that occur in the transition from going ahead to astern are illustrated in Fig. 15. In this example, the main rudder and the auxiliary rudder are both shown making a 0-degree angle with the direction of the ship. Upon reversing the engines, the current swings the main rudder around until it makes an angle of 180 degrees with the ship's head. The successive positions of the two rudders are shown in this figure. When the rudder reaches the 180-degree

Fig. 15

position the auxiliary rudder is ready to take up the control of the main rudder again. It is unnecessary for the helmsman to wait for the rudder to complete its swing. Instead he may immediately turn his wheel for heading the ship in the desired direction after reversing.

SAVING IN POWER EFFECTED

The following considerations indicate how great a saving in power may be expected for the steering gear. Instead of the large main rudder it is only necessary to operate a small rudder having about one-twentieth of the main rudder surface. A further saving arises from the fact that this rudder will not assume positions in which the center of pressure travels far from the axis, while with the normal rudder, under certain circumstances, the center of pressure may even reach the middle of the rudder. Under such circumstances, the strain on the steering gear is very great. Owing to the fact that such exceptional demands are not made on the steering gear with the current actuated rudder, the total saving in power, including also that due to the smaller area of surface moved directly, may amount to 97 percent.

INSTALLATION ON THE FRIGIDO

Toward the end of 1920, the installation of the new rudder was begun by Wilton's Machine Fabriek en Scheepswerf of Rotterdam on the refrigerator ship *Frigido* of the firm of Wm. H. Mueller and Company. Since the spring of 1921, this ship has operated without interruption upon the routes London to Rotterdam, London to Antwerp, and London to Hamburg. The rudder has been proved by test on the *Frigido* in the busy Thames as well as in severe storms on the North Sea.

The operation of the rudder is carried on by hand gear from the bridge. A wire rope lead of 4 millimeters diameter runs from an automobile steering wheel to a small gear box on the hollow main rudder stock. The section chosen for this rudder is that cross section which gives the greatest rudder action for the least movement of the rudder, and has no apparently greater influence on the ship's resistance than the plate rudder.

It must be emphasized that the exact orientation of a rudder to the current has great influence upon the maneuvering power. Since the helmsman cannot take into consideration the changes of direction of the current leaving the ship, frequently the normal rudder is placed in positions very unfavorable for best steering, and furthermore the speed of the vessel is checked. Since the new rudder is influenced by the current, it automatically places itself in such a position relative to the altered current that it draws the greatest steering effect therefrom.

ACTION OF FLETTNER RUDDER STEADIES THE SHIP

A property demonstrated on the *Frigido* is the great steadiness of the rudder action on the ship. This property is due to the very prompt response of the rudder and also to the fact that with the normal rudder, which is fixed, the ship is affected by all the changes in the current about it, both from the waves and from possible changes in the propeller action as the ship is thrown about. As a consequence, the ship is continually being thrown off her course by such influences which cannot be seen by the helmsman. Such behavior is suppressed by the current actuated rudder. The force of the waves has no such effect, since the rudder yields and is then immediately restored to position. It is interesting to observe in heavy weather how the main rudder indicator continually plays back and forth while the ship holds steadily on her course.

A safety factor with the current actuated rudder is the circumstance that the main rudder stock carries no torsion. Nevertheless the dimensions are made in accordance with the rules of the classification societies since they must con-

sider the possibility that the auxiliary rudder may fail. For this same reason, the ship carries the customary emergency steering gear.

Testing Marine Boilers in France

By A. M. Thachara*

ACCORDING to French laws providing for the safety of navigation, new boilers, before being installed in vessels for which they are intended, must undergo a preliminary test at the works of the boiler constructors. The first trial at the works consists of a hydrostatic test at a pressure higher than that at which the boiler will be run under ordinary conditions. This pressure may reach twice the ordinary pressure, but the regulations do not permit excess pressure thus applied to exceed 142 pounds per square inch (10 kilograms per square centimeter).

When installed in a ship, all new boilers must undergo an additional cold water test at a pressure exceeding by one-half that indicated on the boiler as the regulation pressure permitted, but the excess pressure must not be less than 7.12 pounds ($\frac{1}{2}$ kilogram) or greater than 88.3 pounds per square inch (6 kilograms per square centimeter). As a general rule the length of time during which the boiler is subjected to the excess pressure varies from 5 to 10 minutes.

EXEMPTION FROM OFFICIAL TESTS

Boilers which have passed the tests of recognized classification societies and which have been granted a first class certificate by such societies do not have to undergo the above mentioned official tests, as the societies' certificate is accepted by the French government.

*U. S. Consul General, Paris, France.

The Comité Central des Armateurs de France (French Ship Owners' Syndicate) states that the government and classification societies' boiler tests are practically identical, but that the hydrostatic test is not always insisted upon by the societies and that it is left to their experts to decide as to the desirability of such trials. As a result, it sometimes happens that boilers in French ships have never undergone the official hydrostatic test.

According to regulations, steamship boilers are inspected every year, and subjected to a pressure test every four years. The boiler is tested at a pressure equal to one and a half times that indicated and stamped on the boiler as being the normal pressure, but the excess pressure must not be less than 7.12 pounds ($\frac{1}{2}$ kilogram) or greater than 88.3 pounds per square inch (6 kilograms per square centimeter). The pressure test is made by the French authorities, who, however, exempt from such further tests, vessels holding a first class certificate from a classification society.

In addition to the four-year test, trials are likewise imposed by the regulations when boilers have undergone extensive repairs.

DECREASING THE PRESSURE RATING

The proprietor of a vessel is entitled, at the time of inspection of a boiler, or when the four-year test takes place, to request that the pressure rating stamped on the boiler be lowered, if the boiler has already been in use or has undergone extensive repairs or has been in service more than a year since the expiration of validity of the last navigation certificate. In such cases the tests are made on the basis of one and a half times the new pressure rating asked for, the excess pressure not to be less than 7.12 pounds ($\frac{1}{2}$ kilogram) or more than 88.3 pounds per square inch (6 kilograms per square centimeter). If the boiler satisfactorily passes this test, the new rating is stamped on the boiler in lieu and place of the original figure.

Zinc Coatings for Shipbuilding Purposes Galvanizing and Sherardizing

By Horace Holden Thayer*

Continuation of a series of articles containing information regarding shipbuilding materials and their uses that is not readily obtainable from shipbuilding handbooks and other generally available sources. The articles are not intended to be a complete exposition of the subject but will be found to contain items of value to the various classes of workers in this field who have to deal with these materials from the materials point of view.

THIS article has to do with the galvanizing or sherardizing of iron and steel members, fastenings, fittings, etc. of vessels, particularly those subject to salt water or salt air corrosion. A zinc coating is the most permanently efficient practicable method yet devised for protecting iron and steel from such corrosion; and it is therefore used wherever something better than paint or bituminous coatings is demanded. Although such a coating is usually for the purpose of adding to the useful life of the articles coated, it is often also desirable to avoid the streaking and discoloration of adjacent work by rust which would occur if the articles were not properly protected from corrosion. The zinc coating can be applied by hot process galvanizing, electro-galvanizing or sherardizing.

Whatever process is used, the articles have to be thoroughly cleaned, and the surface freed of scale, rust and grease. Acid is usually required in the cleaning process, together with the use of stiff brushes or mechanical tumblers. In some cases sand blasting or sand rolling in tumbling barrels takes the place of the acid. The sand blasting is particularly desirable with porous or bad castings, or where the pickling would impair the strength of the article.

HOT PROCESS GALVANIZING

Hot process galvanizing, which until about the beginning of this century was the only successful method of galvanizing, is accomplished by giving the articles a proper cleaning and drying and then dipping them in molten zinc. Large articles should be preheated so as not to chill the bath. When the articles are withdrawn from the bath, the excess metal is shaken or wiped off, and they are then usually dipped into oil or water. The process is simple, and produces a thick, durable covering of zinc.

This coating is smooth when properly done but has a leamy and sometimes uneven and poor appearance, and paint or other coatings, where required, will not adhere to it until the coating has weathered or been specially treated. Small holes are filled up by this process of galvanizing, and bolt threads and other parts of that nature have to be recut or cleaned out, thus destroying the value of the coating on such parts of the work. The coating is thicker than required for most services, thus being wasteful of zinc. It is generally between 2 ounces and 3 ounces per square foot. There are also considerable losses of zinc in the process. Hot process galvanizing cannot be used for springs and other articles which would lose their temper or be weakened, warped or otherwise injured by the heat treatment.

ELECTRO-GALVANIZING

Electro-galvanizing is simply electro-plating with zinc, and all the technical requirements for successful electro-plating have to be complied with. The surfaces must be chemically clean and the articles must be placed in the plating tanks

in a way to secure good electrical contact and a reasonably uniform deposit of the metal, and be left there a sufficient length of time to obtain the necessary thickness of coating. Up until about 1900 it was considered impossible to obtain a solution, or electrolyte, that with the use of zinc anodes would produce a non-porous and adherent sheet covering of zinc; but about that time inventions embodying the use of special materials in the solution such as a small amount of aluminum, which solved the difficulty, established electro-galvanizing on a commercial basis.

It can be readily realized that electro-galvanizing requires considerably more skill and care than hot process galvanizing, and that in an attempt to expedite delivery or to increase profits the coating may be too thin to afford efficient protection. When well done it is attractive in appearance and can be polished up if desired but all irregularities or imperfections in the surface of the article are faithfully reproduced in the coating. Other coatings, where desired, will adhere well to it.

Electro-galvanizing is particularly desirable for articles that are simple in form, for articles that might be weakened or otherwise injured by heat treatment, for springs, screens, bolts, pipe fittings, etc. Threads do not require recutting after electro-galvanizing. Interior surfaces of articles of considerable length and small cross section are apt to receive only a thin deposit of the metal from anodes outside of the article, and the bottoms of screw threads and similar recessed portions receive less of the metal than the other surfaces.

SHERARDIZING

In the process of sherardizing, the articles to be coated, after thorough cleaning and drying, are placed in a revolving container in an electric furnace with alternate layers of zinc dust. The zinc is first reduced to a gas by the heat of the furnace and this gas solidifies on and partly amalgamates with the surfaces of the articles to be coated. The result is a uniform and particularly efficient anti-corrosive coating. Considerations of practicability and cost usually limit its use for shipbuilding purposes to such articles as are difficult to galvanize properly or which when galvanized would require sufficient subsequent expense for cleaning out, fitting, etc., not required when sherardized. It is particularly desirable for surfaces subject to abrasion and for bolts, nuts, washers and small or intricate pieces that might be filled in by the hot process galvanizing or have some surfaces which would probably not obtain a sufficient thickness of coating by electro-galvanizing. It cannot be used for springs or other articles which would lose their temper or be otherwise injured by the heat treatment.

The coating has a uniform gray color which is attractive in appearance. It is one to which paint, enamel or electro-plating of other metals will readily adhere.

SELECTION OF TYPE OF COATING

Desires of naval architects and other interested parties are apt to be factors in determining the type of coating to use,

*Member of the firm of Rossell & Thayer, naval architects and marine engineers, Philadelphia, Pa.

in addition to considerations of suitability, availability of the process, cost and appearance. Where a vessel is classed the classification society requirements have to be met.

Hot process galvanizing is the method which by virtue of established position may be expected to receive general approval, and there should be no question of the approval of sherardizing for those items for which it is likely to be proposed. In some cases a classification society, owner or naval architect may consider it advisable to require hot process galvanizing of steel fastenings where they would allow electro-galvanizing if the fastenings were of iron, or they might require hot process galvanizing where the vessel is salted and allow electro-galvanizing where the creosote preservative method is adopted, or again they might require the former process for fastenings passing through oak, where the latter would be approved for fastenings through yellow pine. The corroding properties of oak have been referred to in the writer's article in the October, 1921, issue of this magazine. Electro-galvanizing has, however, made such strides in recent years that classification societies may be expected to give it general approval for all purposes for which galvanizing is required for shipbuilding, subject to the usual inspection given all such material in which they are interested and any tests that they may consider advisable to determine whether a sufficient thickness of coating has been obtained.

The U. S. Bureau of Standards in 1918 made a number of tests to determine relative values of hot process galvanizing and electro-galvanizing and the results obtained gave them no reason to believe that for an equal weight of zinc per unit of area the former was superior to the latter. Electro-galvanized specimens taking into account coating thicknesses withstood the salt spray test referred to later as well as, if not better than, specimens galvanized by the hot process, and the average weight losses per day under that treatment were practically identical for the two processes.

TESTS OF ZINC COATINGS

The Bureau of Standards have also tried out different methods of testing zinc coatings. They came to the conclusion that the copper sulphate test for galvanizing or sherardizing was undesirable and that the salt spray method was the most satisfactory. For a quick test to determine the weight of zinc coating they have recommended the antimony chloride stripping test. They consider that the protective value of a coating as shown by the salt spray test is a better indication of its value than the actual thickness of the coating; and have suggested that samples be tested in this way and that if this test indicates a satisfactory coat, similarly treated samples can be stripped of their coating and the amount of zinc be used in checking up the work from day to day by the stripping method, with only occasional salt spray check tests.

These tests are very clearly described in the proceedings of a conference on the electro-plating of military supplies which was held at the Bureau of Standards on March 27, 1918, and the recommendations of this conference together with other valuable conclusions along the line of zinc coatings are here quoted. About fifty persons were present at this conference, representing various branches of the War and Navy Departments, manufacturers engaged on Government contracts, officers and members of the American Electroplaters' Society, and manufacturers of and dealers in plating supplies and equipment. The recommendations are:

1. For protection of iron and steel against corrosion, only zinc coatings should be employed.
2. It is not practical to specify the composition of solutions or conditions of operation to be employed for plating.
3. In the preparation of steel and iron for plating, sand blasting should be given preference to pickling.
4. Some form of corrosion test, such as the salt spray test, should form the primary specification for the quality of zinc

plating; the quantity of coating to be suggested only as a secondary specification.

5. Where the quantity of zinc coating is to be suggested or specified, it should be expressed in terms of weight per unit area (or piece) as determined by some stripping test.

The reasons for and application of the above recommendations were set down as follows:

USE OF ZINC COATINGS

Numerous exposure and accelerated corrosion tests have confirmed the superior value of zinc coatings over copper nickel or brass coatings for protection against corrosion. In view of this fact, it seems highly important that wherever protection of steel against corrosion is an important factor, zinc coatings should be employed. (Note: While this conference was concerned only with electroplating, it should be borne in mind that satisfactory zinc coatings may be produced by hot dipping, sherardizing and electroplating, so-called "electro-galvanizing.")

COMPOSITION OF PLATING SOLUTIONS

Desirable as it might be to insure uniformity of product by specifying the composition of plating solutions and conditions of operation to be employed, such a course is entirely impracticable, for the following reasons: (a) The best conditions of operation have never been definitely determined. (b) A large number of plating plants have neither the equipment nor experience necessary to analyze the solutions and control the conditions of operation. (c) Most platers have become accustomed to certain solutions and conditions of operation, and would find it difficult to obtain satisfactory results under new conditions. (d) Restricting the composition, etc., might exclude many satisfactory processes, and would discourage efforts to improve conditions of operation. Illustrations were given in the conference, of the confusion arising from attempts to specify the exact composition of solutions for black nickel finish.

SAND BLASTING VERSUS PICKLING

It has been frequently shown that under some conditions serious weakening or embrittlement of steel may be produced during the pickling and plating operations. This effect, presumably due to the occlusion of hydrogen, is a surface effect, and is therefore more serious the smaller the cross-section, so that on fine springs, etc., pickling cannot be used. Experiments are in progress at the Bureau of Standards to determine the magnitude of such effects upon steel rods of various sizes and compositions. The results so far obtained upon 3/16-inch rods indicate that pickling under usual conditions reduces the elongation by about 10 percent, while the effects of plating itself are generally much less. In view of this fact it appears desirable to replace pickling by sand blasting (or sand rolling) whenever possible.

CORROSION TESTS

Where zinc plating is applied to steel to produce resistance against corrosion, it is obvious that some form of corrosion test is the only real criterion of the quality of the coating, since the resistance furnished by a given quantity of zinc depends on a number of factors; e.g., the structure, uniformity, continuity, and adherence of the coating, all of which may in turn be influenced by the thoroughness with which the object is cleaned prior to plating. At the present time the "salt spray test" is probably the most reliable means of testing the resistance to corrosion afforded by a zinc coating. In practice the coating should be required to withstand corrosion for a specified number of days when exposed continuously at room temperature to the spray of 20 percent (by weight) sodium chloride solution. The number of days may vary with the needs; e.g., two or three days for articles subjected to moderate exposure, or four days or more for extreme

exposure; e.g., on marine fittings. The essential features of the salt spray test to produce fairly uniform results are as follows:

SALT SPRAY TEST

The salt spray test may be conducted in any convenient non-metallic box or vessel provided with an inclined cover so as to prevent dripping of condensed liquid upon the specimens. A box constructed of Alberene stone, glass, stone-ware, or wood coated with bituminous paint, may be used. (The cut illustrates such a test apparatus.)

The 20 percent salt solution is prepared by dissolving 20 grams of sodium chloride (commercial table salt) in 80 cubic centimeters of water, or 1 pound of salt in 2 quarts of water.

FIG. 2-TOP VIEW

Salt-Spray Box for Accelerated Corrosion

The spray may be produced by any form of air injector which will yield a very fine mist. An air pressure of 6 to 10 pounds per square inch will probably be required. The compressed air should first be passed through water in order to remove dust or grease and to saturate it with water vapor and thereby avoid evaporation of the salt solution. A glass baffle plate should be so placed as to prevent the spray from blowing directly against the specimens. The articles to be tested should each be suspended or supported, for example from glass rods, in as nearly a vertical position as possible, and should not be in contact with metal. They should be removed and washed off at 24-hour intervals or at the end of the specified period of test, and examined for the presence of red or yellow iron rust, the first appearance of which marks the conclusion of the test period. Valuable information may, however, be frequently obtained by continuation of the test to determine the extent of the corrosion on longer exposure.

COPPER SULPHATE TEST

It is recognized that a simpler and more rapid form of corrosion test to determine the quality of zinc coatings, is highly desirable. The Preece test (immersion in copper sulphate solution) was discussed at some length in the conference, and it was generally agreed that while it is of some value under strictly uniform conditions to indicate the thickness or distribution of the zinc coatings, the results of the

test are not sufficiently reliable to warrant its use in specifications.

ANTIMONY CHLORIDE TEST

In some cases it may be desirable to supplement the salt spray requirements by a statement of the quantity of zinc coating probably necessary on a given article to produce the desired resistance. The quantity of zinc coating on any small articles may be quickly determined by a stripping test, e.g., by lead acetate or antimony chloride solution, and may serve as an indication of whether the coating is of uniform weight on different samples, and approximately equal in amount to the coating on similar specimens which have passed the salt spray test. For irregular or threaded parts, the antimony chloride method is recommended. It is carried out as follows: A sufficient number of specimens should be used in each test to have an area of not less than 25 square centimeters (4 square inches). They are weighed (to the nearest milligram) and then dipped in 100 cubic centimeters (or more if necessary to cover the specimens) of concentrated hydrochloric acid (specific gravity 1.20) to each 100 cubic centimeters of which has been added 5 cubic centimeters of a solution made by dissolving 20 grams of antimony trioxide in 1,000 cubic centimeters of concentrated hydrochloric acid. The same portion of hydrochloric acid may be used repeatedly up to five times, by adding before each immersion an additional 5 cubic centimeters of the antimony chloride solution. The samples are immersed in the solution for one minute. They are then washed and scrubbed in running water to remove the deposited antimony, and are dried and reweighed. The loss in weight represents the weight of the zinc coating, which is calculated directly to grams per square decimeter; or to ounces per square foot by multiplying the grams per square decimeter by 0.328 (or for practical purposes, by dividing by 3). Often it may be most convenient, on irregular shaped parts, to express the weight in grams (or milligrams) per piece, thereby avoiding uncertainty as to the exact area of a specimen.

TOLERANCES

Consideration of the tolerances necessary and permissible upon threaded or other dimensioned parts, to allow for the thickness of metallic coatings, showed that the maximum tolerance possibly required (e.g., 0.0025 inch on each surface) will not cause sufficient weakening of the threads as to be objectionable. For most plating applications it is probable that a tolerance of 0.001 inch on each surface will be sufficient.

The Bureau of Standards have supplemented the above mentioned recommendations as to the time that an article should resist the salt spray test by suggesting a test period of about 8 days as desirable for marine work. They have also expressed the opinion that one ounce of zinc per square foot of surface exposed, representing about .0017 inch in thickness, will give satisfactory protection, although as before stated they consider the protective value of the coating as shown by the salt spray test a better indication of its value than the actual thickness of the coating.

NEW AUXILIARY SCHOONER LAUNCHED.—The steel three-masted auxiliary schooner *Hussar*, which is being built from the designs and under the supervision of Cox & Stevens, naval architects, New York, by Burmeister & Wain, Copenhagen, Denmark, for Mr. Edward F. Hutton, New York Yacht Club, was successfully launched on March 15. This vessel, which will be one of the most superb auxiliary yachts in the world, is equipped with a 600 horsepower Burmeister & Wain Diesel engine operating a two-bladed feathering propeller, and will be delivered to Mr. Hutton in the early summer.

The Merchant Marine Problem Can Be Solved

Now Is the Time for Every Real American
to Renew the Fight All Along the Line

By "Old Scotch"

IN spite of a decided majority of the votes in the United States Senate, on every test given, the Administration's shipping bill was killed, through the bitter opposition of a coterie of misguided members, who refused to listen to reason, who absolutely ignored facts and who were determined, fanatically, to kill any kind of a measure which would help the American merchant marine. Their antics demonstrated to the people of the United States that our "most deliberative legislative body on earth" is ruled by a minority, and not by the majority.

It is not for us to rail at the unfairness of the entire Senate procedure, time will bring its own revenge, and the enlightened voters of this country will eventually take care of the men whose machinations in the Senate have made popular government farcical, in this, as well as in several other important legislative programs. Fair minded men would have permitted a vote, but radicals rule for a time, until aroused public sentiment comes to the rescue. Time and again in the history of Congress, this element has thwarted the will of the people, but soon they have returned to the oblivion from which they sprung. So let's dismiss this sore subject from our thoughts and look ahead.

As the experience of the past is the best guide for the future, the men interested in shipping, and especially those in the Government who are managing any legislation for the betterment of the merchant marine conditions, will do well to studiously avoid any more "next session" postponements. People familiar with Washington always take this "next session" talk with a grain of salt, and, in fact, look upon it as tantamount to an acknowledgement of defeat. In this case there seems a well-defined impression that some of the weak-kneed among Republican leaders put it over on President Harding's affable nature by their lamentations of possible defeat if the bill had been pressed during July and August. It could have been passed then, as the climate of the Capitol City has a very enervating and withering effect on filibustering tactics. Long distance talkers, soaked in perspiration, soon shut up. With visions of green fields and fence building at home, the farm "bloc" would have probably succumbed, when the humidity along the Potomac approached the saturation point, as it has a habit of doing in mid-summer.

SHIPPING SHOULD BE NON-PARTISAN ISSUE

Another most important thing to avoid in shipping legislation of the future is the injection of party politics. As no Democrats were called in from the Hill when the ill-fated bill was in the making, the minority party naturally concluded that it was to be passed as a purely Republican measure. Partisan politics are never injected in legislation for the Army and Navy, and the merchant marine is just as much a national issue as are these two great arms of the national defense.

Neither the Republican nor the Democratic party platforms is ever framed without the inclusion of a plank pledging the respective parties to the upbuilding of American shipping. True, they generally differ as to the means advocated, but they have the same patriotic object to accomplish. Such a spectacle as the minority party calling a caucus and deciding on party opposition should never be allowed to occur again. The political differences should be threshed out before the introduction of the bill, and then let it be considered on its merits alone.

The one outstanding feature of all the debates on the late bill, was that no one seriously antagonized the idea of our having our own ships to carry our own products to foreign markets. In fact had a vote been taken on that question in the abstract it is doubtful if it would ever have been necessary to have had a roll call on the subject, as the sentiment in its favor would practically have been unanimous.

With such a sentiment as a decided asset for the proponents of an American merchant marine, and with eight months' time intervening before Congress again assembles in regular session, it behooves all elements interested in advancing our shipping to get together and formulate a policy which will arouse no opposition of a partisan nature. From statements in the public press, Chairman Lasker is quoted as saying that a new bill will be prepared and presented to the next Congress by the President in December. Just what form such a measure will take is, at this writing, a matter of great conjecture. In addition to the many real experts now in the Shipping Board, there seems but little doubt that before any measure is decided upon, the opinions of experts outside the governmental circles will be asked and given serious consideration.

PREFERENTIAL DUTIES OF DOUBTFUL VALUE

Means for accomplishing the desired end are by no means exhausted in the failure of the so-called subsidy bill. Differential duties on imports are still authorized, and need but the annulment of some existing treaties to be put in effect. Now that this procedure is a possibility without further Congressional action, many shipping men are giving the subject serious consideration. Many well-informed men are doubtful as to the ultimate benefits to be derived from a reduction of duties on imports, if the goods are carried in American bottoms, for the reason that our principal imports are not of a bulky nature. While our exports reach an enormous tonnage, the same cannot be said of imports, for the reason that many of them come under the characteristics of luxuries or semi-luxuries and, in consequence, are valuable but not very bulky. For example, the following imports arranged according to value, have been received at our great port of importation, New York city, during the past six months:

Sugar, tobacco, woolen fabrics, cotton fabrics, vegetable fibers, diamonds and precious stones, silk manufactures, china and earthenware, fruit and nuts, clocks and watches, iron and steel manufactures, drugs and chemicals, perfumery and cosmetics.

Sugar, of course, is dutiable and of great bulk; it therefore would encourage considerable American tonnage. Manufactured silk, diamonds and precious stones, clocks and watches, drugs and chemicals, etc., on the contrary while of considerable intrinsic value would do but little to encourage shipping, owing to the small weight and volume entailed in their transportation overseas.

Customs differentials would, of course, help considerably but without other governmental aid it is doubtful if they would solve our problem.

SALE OF VESSELS AT LOW RATE WILL HELP

It is within the power of the Shipping Board to establish real help for the next few years, at least, by selling the b

the ships to private American owners, at such a low rate that the interest, depreciation and insurance charges would be so small as to offset in the operating costs, the proposed direct aids contained in the recent ill-fated Merchant Marine Act of 1922. Naturally such a procedure would provide nothing for the highly essential replacement fund which all successful private corporations must consider. It would also work an injustice to the so-called pioneer purchasers of Shipping Board tonnage, except that by the purchasing of additional tonnage from the same source at much lower rates, the average cost of their equipment would be greatly lowered. Consideration should be given to the possibilities of utilizing enlisted men from the regular Navy to man ships in the foreign trade, on the basis of a Naval Reserve, the Government to pay half their wages and the private shipowners the remainder. As it is incumbent upon the Navy to operate private shipping in times of war, it cannot be denied that the training of men to operate merchantmen is as essential as it is to train them to operate purely fighting craft. Such an arrangement would quite manifestly overcome the wage differential between American and foreign ships. Many of our competitors now adopt this method although the proportion of pay from the governments involved is much less than herein proposed.

REMOVE THE INEFFICIENT TONNAGE

A great deal of discussion is now going on as to the disposition of the useless idle tonnage. The proposal to get rid of some 400 or 500 of the least efficient ships by scrapping or sinking at sea is one that should be given most careful attention. There is no doubt whatever that such craft should be withdrawn from any possible commercial usage, for the best interests of all concerned. But to deliberately sink that many craft, where there is no possible chance of further usage, even in time of possible great emergency, is a very serious question.

Would it not be better to select out the unfit vessels, withdraw them from any possible sale in time of peace, and store them as far as possible up some of the many available rivers, where the water is entirely fresh? A dozen men employed to prevent pilferage should suffice for each hundred of these ships. If we but recall how many vessels, which had been

stranded for a number of years, were floated, patched up, and performed really valuable services when the great demands incident to war were on, it is not difficult to conclude that even for a period of ten years, these partly abandoned vessels might prove to be a great asset should any future emergency arise when the whole world may be clamoring again for "Ships, ships and yet more ships."

True, it might be necessary to provide new boilers, condenser tubes, and other parts vulnerable to the ravages of oxygen, but the point is that without any care involving expense, the hulls and heavy parts of machinery of such ships stored in fresh water, would be fit to use again. It would be much cheaper to patch up such old hulks than it would be to construct entirely new vessels at the inflated prices attending all great emergencies.

The setback we have received by the inanition of the Senate should not discourage us. We have received similar jolts before, but realizing that we are right, we should all keep up our courage and renew the fight all along the line.

Propellers

(Continued from page 222)

a high figure for the resistances of the ship and is therefore of very little value for the purpose of arriving at true figures.

Owing to the very small actual twist in a ship's shafting, readings by torsion meter are naturally very small and when a ship is laboring at sea they become quite definitely inaccurate. For this reason some better means of arriving at the Q.H.P. might be tried, such as the use of an electric or mechanical flexible coupling, the displacement of the two flanges being calibrated for torque before installation on board ship.

The Shipping Board can do no greater favor to the ship operating industry than to initiate accurate tests on one or two freight ships. First, in the tank, with and without propeller, and later with instruments for carefully recording both the torque and the thrust. Tests with this device would have to be made at all speeds in smooth water over a deep water course and this could then be carried out also on one transatlantic voyage.

The First Vessels for the Irish Navy

(Photograph by Kadel and Herbert, N. Y.)

The three vessels shown in the above illustration are the first ships purchased by the Irish Free State. They are the first vessels to fly the Irish ensign, and will be fitted out as gunboats for patrol work.

Current Admiralty Decisions of Special Interest

By Calvert B. Gill*

Breach of Affreightment Contract

THE rights and liabilities of the parties depending on general rules of maritime law are not subject to material alteration by State enactments declaring vessels navigating the waters of the State subject to a lien for damages resulting from nonperformance of affreightment contracts. The lien against a vessel for damages resulting from a breach of an affreightment contract does not attach before the cargo is delivered to and received on board the vessel.

Since the lien on a vessel for damages caused by a breach of an affreightment contract and the lien of the vessel on the cargo for the freight are mutual and reciprocal, receipt of part of the cargo called for by the contract does not entitle the shipper to a lien on the vessel for damages caused by its refusal to receive the rest of the cargo called for by the contract. *Osaka Shosen Kaisha et al. vs. Pacific Export Lumber Company*, 43 Supreme Reporter, 172.

Necessary Act of Sacrifice Comes Under General Average

ALL losses in a maritime adventure falling outside the contractual obligations of the parties and which arise from a voluntary sacrifice of a part of the cargo, made to save the whole adventure from perishing, or which arise out of extraordinary expenses or expenditures of money incurred for the joint benefit of both ship and cargo constitute a claim to general average contribution. It was said in the case of *Aktieselskabet Fido vs. Lloyd Brasileiro et al.*, 283 Federal Reporter, 62, that where a charterer, who had chartered the vessel for transportation of coal, delivered sufficient cargo at port of discharge under previous charter for stiffening but the coal so delivered was overheated at port from which the coal was to be transported, requiring the discharge of such coal and the loading of entirely new cargo, the loss caused by the delay constituted a claim to general average contribution since there was an imminent peril common to all interests, a voluntary, deliberate and intentional necessary act of sacrifice or expenditure made to preserve all interest and the act was attendant with success and the peril avoided.

Where a Release Signed by a Seaman Should Be Set Aside

THE release signed before a shipping commissioner by discharged seamen on settlement of their wages for the time served, as required by the Revised Statutes of the United States, section 4552, does not operate as a consent to their unlawful discharge. Although section 4552 provides that a release signed by a seaman thereunder on receipt of wages, "shall operate as a mutual discharge and settlement of all demands for wages," the Seamen's Act of March 4, 1915, section 4, provides that the court may upon good cause being shown, set aside such release and take such action as justice shall require. It was said in the case of

Brown et al. vs. United States, 283 Federal Reporter, 425, that where seamen discharged without their consent or fault before commencement of the voyage, who were entitled under the Revised Statutes of the United States, section 4527, to an additional month's wages, were compelled to sign such a release to obtain payment of the wages admittedly due them, the release would be set aside and held not a bar to their recovery under section 4527.

Concerning Changes in Wages

WHEN shipping articles have a provision in them, providing that the wages named were subject to change in accordance with a new scale to be adopted by shipowners, the court declared in *Jones vs. United States*, 284 Federal Reporter, 721, that the articles were invalid as they did not comply with the statute requiring the articles to state the wages to be paid, notwithstanding Revised Statutes of the United States, section 4511 provides that the articles may contain stipulations in reference to advance and allotment of wages, or other matters not contrary to law.

Injuries Sustained by Stevedoring Employees

IN *Farrell vs. Waterman Steamship Corporation et. al.*, decision of January 25, 1923, the court says, that District Courts have jurisdiction in Admiralty of personal injury cases concerning employees of stevedoring companies notwithstanding the Act of Congress of June 10, 1922, as the provisions of the Act, denying to District Courts jurisdiction in cases of injuries to persons other than the master or crew of vessels for which compensation is provided by State acts, are unconstitutional under Article 3, sections 1 and 2 of the Constitution of the United States.

Ship's Liability When in Charge of Stevedores

ASHIP, in safe condition when placed in charge of a stevedoring company as an independent contractor for discharging and loading, is not liable in Admiralty for injuries to employee of such company by falling through a hatchway due to the negligence of the stevedoring company in leaving the hatchway uncovered after work had ceased at night and insufficiently lighted and also to contributory negligence of the employee, who knew of the open hatchway and with due care would have avoided it. *The Kongosan Maru*. 282 Federal Reporter, 666.

Seamen's Liability Cases in State Courts

ALTHOUGH the liability of an employer to a seaman injured in his employment was defined by the maritime substantive law, it was said by the court in *Bonam vs. Southern Menhaden Corporation*, 284 Federal

*Attorney at law, Baltimore, Md.

Reporter, 362, that where the seaman elected not to seek redress in Admiralty, but to come into the law court, his remedial rights were governed by the procedure of the latter court and as limitations pertain to the remedy and not to the right, the defendant had the right to invoke the statute of limitations of the State, where there was no Federal statute of limitation. As there are no statute of limitations in Admiralty, the court may, in its discretion, apply the doctrine of laches as equivalent so that statutes barring old or stale claims are persuasive, but not controlling in Admiralty cases.

Properly Manned Condition Should Be Strictly Construed

THE Harter Act, section 3, exempting a ship and owner from liability for loss resulting from faults or errors in navigation, if due diligence has been exercised to make the ship seaworthy and properly manned, equipped and supplied, should be strictly construed, says the court in *The Port Morgan*, 284 Federal Reporter, page 1, especially where exemption is claimed for losses due to stranding of the ship which was caused by the gross negligence of the engine room force, which had been selected by the owners without exercising the proper care required by the Harter Act in equipping and manning a ship.

Payment for Towage Contract

WHERE a contract for towage was made with charterer's undisclosed principal and one-half thereof was paid by such principal within thirty days after rendition of services and the principal was granted an extension of time for the payment of the other one-half, but payment thereof was not made because of the insolvency of the principal and where the charter provided for the payment of towage by charterer, there was no maritime lien for the unpaid one-half of the towage, even if a claim for towage could be maintained as a necessity within the Act of June 23, 1910, giving a maritime lien for necessities. *The Mona*, 282 Federal Reporter, 468.

GREAT LAKES VESSEL LAUNCHED.—Specially designed for service on the Canadian Lakes and canals the *Glencorrie*, a single screw steamer, was successfully launched by Swan, Hunter, & Wigham Richardson, Ltd., from their Wallsend Yard on March 1. The principal dimensions are 250 feet in length between perpendiculars, 42 feet 6 inches in width, with a molded depth of 20 feet 6 inches. Water ballast will be carried in the fore peak and in the double bottom fore and aft. The propelling machinery consisting of a triple expansion engine and two single-ended Scotch boilers built by MacColl and Pollock, Ltd., Sunderland, is located aft.

Questions and Answers Relating to Naval Architecture and Marine Engineering

Conducted by James L. Bates, Naval Architect, and W. B. Newton, Marine Engineer

This department is maintained for the purpose of answering all questions relating to ships and their machinery. All inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

Determining the Strength of a Hollow Shaft and Coupling

Q. (1188).—Will you please show me how to find the strength of a hollow shaft and the strength of a coupling to suit a hollow shaft?—L. T.

A. (1188). To better illustrate the method to be followed in the design of marine shafting, an actual case of a hollow line shaft with its coupling will be worked out for a triple expansion three cylinder engine of 1,800 indicated horsepower and 90 revolutions per minute.

A = actual metal area of shaft cross section, square inches.

D = diameter of hollow shaft in inches.

D_s = diameter of solid shaft in inches.

E = effective thrust on shaft in pounds.

$E.H.P.$ = effective horsepower for designed speed of vessel.
= 0.55 (assumed) $\times$ 1,800 = 990.

F = weight of shaft per running inch, in pounds.

L = greatest distance from center to center of bearings in inches = 144 (assumed).

S = speed in knots = 14.

T = maximum twisting moment on shaft, inch pounds.

d = diameter of shaft bore, in inches (= $0.6 \times D$ assumed).

f = maximum allowable combined stress, pounds per square inch = 5,500 (60,000 pounds material assumed).

f_b = bending stress due to own weight, pounds per square inch.

f_s = shearing stress due to torsion, pounds per square inch.

f_t = compressive stress due to thrust E , pounds per square inch.

k = constant depending upon number and arrangement of cylinders.

= 1.8 for single crank.

= 1.4 for two cranks at 90 degrees apart.

= 1.32 for three cranks at 120 degrees apart.

$0.92 \times I.H.P. \times k \times 63,024$

$T = \frac{\text{R.P.M.}}{\text{R.P.M.}}$

$0.92 \times 1,800 \times 63,024$

90

$S.H.P. \times 63,024$

(T for turbine shafts = $\frac{\text{R.P.M.}}{\text{R.P.M.}}$)

A rough estimate should first be made to determine the shaft diameter based upon solid shaft calculations.

$$D_s = \sqrt[3]{\frac{5.1 \times T}{f_s}} = \sqrt[3]{\frac{5.1 \times 1,159,700}{5,500}} =$$

10.24 square inches.

To determine the approximate outside diameter of a hollow shaft of the same strength, proceed as follows:

Where diameter of hole = $0.4 D$ add 1 percent
= $0.5 D$ add 2 percent
= $0.6 D$ add 5 percent
= $0.7 D$ add 10 percent } to D_s

Therefore $D = 10.24 \times 1.05 = 10.75$

As the above calculations do not take into account bending and compressive strains it is safe to assume our shaft will be at least 11 inches diameter.

Shaft Diameter, Inches

D (assumed)	11	12	13
$d = 0.6 D$ (use nearest even value)	6.625	7.25	7.75
$D^4 =$	14,641	20,736	28,561
$D^2 =$	121	144	169
$d^4 =$	1,926	2,763	3,608
$d^2 =$	43.89	52.42	60.06
$L^2 =$	20,736	20,736	20,736
$E.H.P. \times 33,000$			
$E = \frac{S \times 101.33}{4 F L^2 D}$	23,030	23,030	23,030
$F =$	17.21	20.40	24.30
$f_b = \frac{\pi (D^4 - d^4)}{4 F L^2 D}$	396	360	334
$A =$	60.56	71.82	85.56
$f_t = \frac{E}{A} \left(1 + \frac{16 L^2}{25,000 (D^2 + d^2)} \right)$	448	367	302
$f_s = \frac{5.1 T D}{D^4 - d^4}$	5,156	3,943	3,080
$f_a = f_b + f_t$	844	727	636
$f = \frac{1}{2} f_a + \frac{1}{2} \sqrt{f_a^2 + 4 f_s^2}$	5,545	4,324	3,416

Plotting values of D against values of f , the outside diameter D corresponding to the designed stress of 5,500 is found to give a diameter of 11.03 inches. The shaft would be 11 inches outside diameter and 6 $\frac{5}{8}$ -inch bore.

The material of the coupling will be taken as cast steel with a maximum tensile strength of 60,000 pounds per square inch.

Working stress allowable = 5,500.

Keys to be of same material as the shafting and designed for a safe crushing load of 11,000 (f_c) pounds and a shearing load of 4,500 (f_s) pounds per square inch.

D_1 = diameter of shaft in hub = $1.1 \times D = 1.1 \times 11$
= 12.1 inches, approximately 12 $\frac{1}{8}$ inches.

W = width of key.

B = length of key.

n = number of keys

	1	2	3	4
$B \times b = \frac{2 T}{D_1 \times f_c \times n}$	17.38	8.69	5.793	4.345

	42.5	21.25	14.17	10.625
$W \times B = \frac{2 T}{D_1 \times f_s \times n}$				

$$\frac{2.445}{b} = \frac{2.445}{2.445} = \frac{2.445}{2.445} = \frac{2.445}{2.445}$$

$$\text{one key} = \frac{d}{4} + \frac{1}{8} \text{ inch}$$

$$\begin{cases} \text{two keys} = d/5.5 + \frac{1}{8} \text{ inch} \\ \text{three keys} = d/7 + \frac{1}{8} \text{ inch} \\ \text{four keys} = d/8.5 + \frac{1}{8} \text{ inch} \\ \text{Use one key.} \end{cases}$$

$$W = \frac{D}{4} + \frac{11}{4} \text{ inch} = \frac{11}{4} + \frac{1}{8} \text{ inch} = 2\frac{7}{8} \text{ inches}$$

$$\begin{aligned} b &= 2.875 \div 2.445 = 1.176 = 1 \frac{3}{16} \text{ inches} \\ B &= \text{length of key, also length of hub} = 17.38 \div 1.1875 \\ &= 14.64 \text{ inches} \\ &= 14\frac{5}{8} \text{ inches} \end{aligned}$$

$$\begin{aligned} D_2 &= \text{diameter of hub} = \frac{4T}{f_s D_1 B} + D_1 + 2b \\ &= \frac{4 \times 1,159,700}{5,500 \times 12.125 \times 14.625} + 12.125 + (2 \times 1.1875) \\ &= 19\frac{1}{4} \text{ inches.} \end{aligned}$$

The maximum permissible length of the coupling should be about 4 times the hub thickness.

Assume no taper to coupling bolts and the material to have a 60,000-pound maximum tensile strength. Safe shearing stress = $f_s = 4,500$ pounds per square inch.

$$\begin{aligned} d_1 &= \text{diameter of bolt, inches} = 1\frac{3}{4} & 2 & 2\frac{1}{4} \\ d_2 &= \text{nuts across corners} = 3.1875 & 3.594 & 4.031 \end{aligned}$$

$$c = \text{clearance between nut and hub, inches} = \frac{5}{8} \quad \frac{3}{4} \quad \frac{7}{8}$$

$$c_1 = \text{corner of nut to flange edge, inches} = \frac{3}{8} \quad \frac{3}{8} \quad \frac{3}{8}$$

$$\begin{aligned} D_3 &= \text{diameter of bolt circle, inches} \\ D_2 + 2c + d_2 &= 23\frac{3}{4} \quad 24\frac{3}{8} \quad 25 \end{aligned}$$

$$\begin{aligned} A &= \text{shearing area of bolt, square inches} = 2.405 \quad 3.142 \quad 3.976 \end{aligned}$$

$$P = \text{load at bolt circle} = \frac{2T}{D_3} = 97,660 \quad 95,160 \quad 92,760$$

$$N = \text{number of bolts} = 8 \quad 8 \quad 8$$

$$f_s = \frac{P}{8 \times A} = 5,075 \quad 3,785 \quad 2,916$$

Use eight 2-inch diameter bolts.

$$\begin{aligned} D_4 &= \text{diameter of flange} = D_3 + d_2 + 2c_1 \\ &= 24\frac{3}{8} + 3\frac{5}{8} + (2 \times \frac{3}{8}) = 28\frac{3}{4} \text{ inches.} \end{aligned}$$

The flange thickness is usually based upon an empirical proportion.

$$= 1.35 d_1 \text{ for cast iron}$$

$$= 1.15 d_1 \text{ for cast steel and wrought steel.}$$

$$= 1.15 \times 2 = 2.3 \text{ inches, use } 2\frac{3}{8} \text{ inches.}$$

It is assumed in your problem that I.H.P. (indicated horsepower) was inadvertently used in place of S.H.P. (shaft horsepower) as the shaft is for a turbine and not a reciprocating engine.

$$T = \text{maximum turning moment} = \frac{\text{S.H.P.}}{\text{R.P.M.}} \times 63,024$$

$$= \frac{7,500}{570} \times 63,024 = 829,400 \text{ inch pounds.}$$

$$D = \text{diameter of shaft, inches} = 7$$

$$d = \text{diameter of shaft bore, inches} = 3.5$$

$$f_s = \text{stress due to torsion, pounds per square inch} = \frac{5.1 T D}{D^4 - d^4}$$

$$\begin{aligned} &= \frac{5.1 \times 829,400 \times 7}{(7)^4 - (3.5)^4} = 13,153 \end{aligned}$$

The shaft material has a maximum tensile strength of 62,000 to 70,000 pounds which would not permit of a working stress of over 5,700 to 6,500 pounds per square inch. The shaft is therefore too small for good marine practice.

The above work is believed to be in sufficient detail as to method to enable you to work out your own coupling stresses as space does not permit of further discussion of the subject.

NEW BOOKS

Diesel Engines for Land and Marine Work

Reviewed by L. R. Ford*

DIESEL ENGINES FOR LAND AND MARINE WORK. (Fifth edition). By A. P. Chalkley. Size, 5 by 8½ inches. Pages, 330. Illustrations, 161. New York, 1922: D. Van Nostrand Company.

This book as originally issued was the admirable result of the effort of the author to meet the need for a treatise that would supply a fund of general information to both the technical reader and the non-technical seeker after information regarding the Diesel engine.

The increasingly widespread use of the Diesel engine and the fact that practically all important marine engineering firms are prepared to manufacture it in one form or another have resulted in the development of new types and the improvement of old ones, to such an extent that the author has found it necessary to revise the book in order to bring it up to date. Notwithstanding the intensive development of the Diesel engine and the great refinement of mechanical details that has resulted, the basic principles of Diesel engine design, manufacture and operation have not changed enough, to require any change in the text in the first six chapters of the book.

Chapter seven has been entirely re-written and enlarged and it is now a profusely illustrated description of most of the leading types of engines, including the latest and most radical departure from conventional design, the Still combined Diesel and steam engine. Chapters eight and nine are but slightly changed from the original editions.

It is to be regretted that, apparently in order to save space, the section devoted to small Diesel marine engines was glossed over very hurriedly. The development of these small engines has been so great since the first edition of the book that the author would have been justified in expanding this section to make an additional chapter. Such engines as the Leissner, Worthington, Berrz, Hvid, Crossly, Deutz, etc., are being produced in such numbers that the total horsepower in operation already probably exceeds that of the larger types but they have not received notice in the book. It is perhaps unfair, however, to demand more when the author has collected so much valuable information.

The outstanding physical feature of the book is the number and clarity of cuts with which the text is illustrated.

Only enough space is given to theoretical considerations to enable the reader to understand the why and the how of engine operation and the book should be of great value to the very large number of operating steam engineers who are seeking general information regarding the Diesel engine and especially to the marine steam engineers who wish to qualify

*Manager of Diesel engineering department, Morse Dry Dock and Repair Company, Brooklyn, N. Y.

for examination for license as Diesel engineers. To the technical reader the book's chief value is as a source of information regarding general details of construction as worked out by the various manufacturers.

The author's treatment of his subject indicates a very broad knowledge of practical Diesel engineering and everyone who has been for years familiar with his book in its various editions will welcome the new and up to date information contained in this enlarged edition.

PERSONAL MENTION

C. S. DORAN, vice-president and general manager of the Sperry Gyroscope Company, Brooklyn, N. Y., recently sailed for England.

H. J. BRADLEY has been appointed San Francisco branch manager of the Chicago Pneumatic Tool Company to succeed J. K. Haigh.

J. F. BORELAND, vice-president of the Huhn Manufacturing Company, New York city, is on an extended business trip to Japan and Hawaii.

A. P. LANE, fuel director of the State of Maine, was recently elected for membership to the Maritime Association of the Boston Chamber of Commerce.

D. A. DECROW, manager of the Water Works Department of the Worthington Pump and Machinery Corporation, New York, recently died at his home in East Orange, N. J.

CAPTAIN HERBERT HARTLEY, commander of the American liner *St. Louis* during the war, has been appointed master of the *Leviathan*. As master of this liner, which will be placed

Captain Herbert Hartley

in the New York-English Channel service under the flag of the United States Lines probably in June, Capt. Hartley becomes commodore of the largest fleet of passenger vessels under the American flag.

WALTER MAUGHAN has been appointed manager of the steamship passenger business of the Canadian Pacific Railway on both the Atlantic and Pacific oceans. During the war Mr. Maughan did valuable work as chairman of the Demobilization Committee of the Canadian Railway War Board representing the Minister of Militia and was made a

lieutenant-colonel in recognition of his work in the transportation of troops from Canada and China to France. Mr. Maughan was born in Toronto in 1876 and joined the Canadian Pacific forces in 1892. In 1897 he was made city passenger agent at Toronto and in 1913 district passenger agent. In the same year he was moved to Montreal as assistant general passenger agent and in December, 1922, became assistant to the general passenger traffic manager.

CALVIN AUSTIN, president of the Eastern Steamship Lines, Inc., has been elected president of the Old Dominion Steamship Company, recently acquired by the Eastern Steamship Lines. H. H. Walker, of New York, formerly president of the Old Dominion Line, has been elected vice-president.

JOSEPH S. JONES, who was recently appointed vice-president of Charles Cory and Son, Inc., New York, was born in Norfolk, Va., on March 1, 1888. His academic and

Joseph S. Jones

technical education was obtained at St. Mary's Academy and Columbia University. Mr. Jones served a special apprenticeship course in naval, electrical and mechanical engineering at the Navy Yard, Norfolk, Va., for which he received the Secretary of the Navy's certificate and award. The positions that have been held by Mr. Jones are as follows: Hull draftsman, Navy Yard, Norfolk; electrical draftsman; electrical expert aide; senior electrical expert aide and assistant electrical superintendent; electrical superintendent (acting) in charge of

naval electrical work including the fitting out of transport and the conversion of the ex-German liners in the Third Naval District to troopships; engineer and assistant to the vice-president, Charles Cory and Son, Inc., and general commercial manager and assistant to the president of the same company since 1921.

Mr. Jones has invented several mechanical improvements and equipment in the marine field, the principal of which are an electro-mechanical dry dock control system which is the first and only system of its kind in use; special watertight indicating rotary snap switches; a cutting machine for removing the cover on leaded and armored cable; watertight lighting fixtures; train semaphore signal system; valve position indicating system; watertight deck plug and receptacle; system of installing storage batteries in submarines interior fittings for watertight connection boxes.

He is also author of several technical and scientific treatises covering various types of signaling and power equipment for the Navy Department; specifications used in connection with the conversion of merchant vessels to transport and the electrical work required for preparing ex-German ships for the transport service. He is also author of "Ship Telegraphs and Their Uses." Mr. Jones served in Battery B, First Battalion, Virginia Field Artillery for four years (Norfolk Light Artillery Blues). He is a member of the American Institute of Electrical Engineers, Society of Naval Architects and Marine Engineers, New York Southern Society, the Virginians, New York Electrical League, the Old Colony and the Knickerbocker clubs.

The Month's Shipping and Shipbuilding News in Brief

Shipyard, Steamship and Port Activities and Other Notes
of Interest in All Branches of the Marine Industries

Seventeen Millions in Ship Work

APPROXIMATELY seventeen million dollars in ship construction and reconditioning work is either about to be placed or is under serious consideration for the near future, according to latest information obtainable by MARINE ENGINEERING AND SHIPPING AGE. These figures, while forming a necessarily tentative estimate of the total involved, provide for the construction of five combination passenger and cargo ships and the reconditioning of six others.

The situation in regard to new construction is as follows: preliminary plans are in course of preparation by Theodore E. Ferris, naval architect and marine engineer of 30 Church Street, for two passenger and freight ships for the Clyde Line; two passenger and freight ships are contemplated for the Old Dominion Line; bids were received on March 20, and are now under consideration, for the building of one ship for the New York & Porto Rico Line. Tenders are also being received for the building of five self-propelled barges and forty cargo barges (all of steel construction) designed by the firm of Kindlund & Drake, naval architects and marine engineers of 17 Battery Place. The probable cost of these vessels as well as eight ferryboats to be built for the City of New York is not included in the figures given above.

In reconditioning work the market shows decided improvement with the outlook much brighter than it has been in many weeks. Contracts next in size to the *Leviathan* job are seen in the proposed reconditioning of the *Agamemnon* and *Mount Vernon*. The firm of Gibbs Brothers, Inc., No. 1 Broadway, who prepared the plans and specifications for the *Leviathan* work, have accepted a like contract in relation to the *Agamemnon* and *Mount Vernon*. Additional steel construction work on the hulls of these ships to increase their stability is under investigation, which, if carried out, will add materially to the original cost estimates.

Shipyards are at present preparing to submit bids on April 2 for the thorough reconditioning of the steamer *President Buchanan* and plans and specifications have been issued from the Shipping Board, at 45 Broadway, for the carrying out of alteration and additions to the steamship *President Adams*.

\$100,000,000 Asked for New York City Issues Plans and Specifications for Eight Ferryboats to Cost \$1,475,000

ACCORDING to the last bulletin of the Atlantic Coast Shipbuilders' Association, the Navy Department in the preliminary estimates for the next budget asking for an appropriation of almost \$100,000,000 for auxiliary craft, cruisers and submarines.

These estimates are a part of the policy which has been recommended by the General Board for the purpose of bringing the United States Navy up to treaty strength in auxiliary craft. The entire program, which probably will be worked out on a three-year basis, calls for sixteen light cruisers of 1,000 tons with eight-inch guns and twenty-four submarines of 2,500 tons, half mine layers and half scouts, the cost of the completed program will approximate \$300,000,000. The General Board recommends that six or eight of the cruisers and six of the submarines be provided for by the next Congress.

Bids Open April 12 for River Towboat Hull

SEALED proposals will be received by the United States Engineer Office, Rock Island, Ill., until 11 A. M., April 12, furnishing and delivering one steel hull for the towboat *Elinor*.

PLANS and specifications for the construction of eight steel screw ferryboats have been issued by the Department of Plant and Structures of the City of New York. It is estimated that the total cost of the contract will be close to \$1,475,000. The amount of security to guarantee the faithful performance of the work will be \$50,000 for each boat and the first boat is to be delivered, entirely completed, within 140 consecutive days from the date of certification of the contract and thereafter one boat is to be delivered complete every twenty days.

GENERAL DIMENSIONS

The specifications (A, B, C and D) provide for the construction, equipment and delivery of eight ferryboats, each having a length over guards of 130 feet, beam over guards 52 feet, beam of hull molded 36 feet, draft 8 feet 6 inches. The vessels are to be double-ended, constructed for the carrying of passengers and vehicles, each boat having three team gangways and two cabins on the main deck. The vessels are to be constructed according to the requirements of the American Bureau of Shipping.

SPECIFICATION "B"

Specification "B" provides for the installation of single expansion, non-condensing steam engines for propulsion and steam operated auxiliaries, steam being generated in fuel oil fired boilers together with all necessary piping, fitting, etc., the hulls to be as specified with such modification as may be necessary for the proper installation of such machinery and equipment as called for in the specification.

Under this specification each engine is to have two cylinders not less than 16 inches in diameter and a stroke of not less than 18 inches, the engine developing sufficient horsepower at a speed of 180 revolutions per minute and at a steam pressure of 125 pounds to drive the boat at a speed of ten nautical miles an hour. The propellers are to be of open hearth cast steel, the shafts being of forged steel. There are to be two tanks for fuel oil, having a total capacity of 8,000 gallons and also two water tanks, having a capacity of not less than 1,500 gallons each.

Each boat will have two approved Scotch marine boilers not less than 7 feet in diameter by 11 feet 6 inches long, the boilers

to pass the requirements necessary for 180 pounds working pressure.

EQUIPMENT

Each boat will have an approved feed water heater of the multicool type, cast iron shell and copper or brass tubes, and to be arranged to take exhaust from the main engine; two approved horizontal feed pumps, $7\frac{1}{2}$ by $4\frac{1}{2}$ by 10 duplex or equivalent, pumps to be brass fitted; one approved horizontal fire pump, $7\frac{1}{2}$ by $4\frac{1}{2}$ by 10 duplex or equivalent, also to be brass fitted; Ashton type safety valves; boats to be steam heated, electrically lighted; life boats and similar equipment, according to United States laws.

SPECIFICATION "C"

Specification "C" provides for the installation of compound condensing engines for the propulsion of the vessels and steam operated auxiliaries, steam being generated in fuel oil fired boilers, together with all necessary pipings, fittings, etc. In this case, the boats are to have two approved compound, 2-cylinder engines with all appurtenances, the cylinders to be not less than 12 inches with 24 inches diameter and the stroke not less than 18 inches.

EQUIPMENT

Under this specification the equipment will include: the air pump, $7\frac{1}{2}$ inches by 14 inches by 10 inches; vertical simplex beam air pump, having one steam cylinder, brass fitted throughout; one main condenser, independent of main engine; the cooling surface to be at least 1,200 square feet measure on the outside of the tubes; and one side inlet centrifugal pump of sufficient capacity, direct connected to an engine of sufficient power.

SPECIFICATION "D"

Specification "D" provides for propulsion of each boat by a vertical 6-cylinder, single acting, direct reversing, heavy duty oil engine (marine type) in which ignition is dependent solely on the temperature of compression. The engine must be of suitable design for direct connection to propeller shafting at both ends. The engine must be guaranteed to develop sufficient shaft horsepower to drive the boat at ten nautical miles an hour with piston speed under 760 feet per minute at revolutions not to exceed 190 per minute.

The boats, under this specification, are to be equipped with an approved generator having a continuous duty rating of 40 kilowatts, 115 volts at the normal speed of the engine, direct connected to an approved vertical fuel oil engine to provide current to light the boat and to drive the following motor driven auxiliaries with which the boat is to be equipped.

Auxiliaries	Horsepower of Motor
Two steering engines.....	8
Circulating water pump.....	5
Fire and general service pump.....	10
Maneuvering air compressor.....	15
Fuel oil pumps.....	5

Each boat is also to be equipped with the following motor driven auxiliaries, connected up and ready for use: auxiliary air compressor with a capacity of 40 cubic feet of free air per minute; circulating water pump, with a capacity of 7,500 gallons per hour with a reserve unit of equal capacity; fuel oil pump, with a capacity of 2,100 gallons per minute with a reserve unit of equal capacity.

Electric steering engines of approved design are to be provided and each boat will be equipped with an approved fuel oil burning boiler with piping of sufficient capacity to heat the cabin and pilot houses.

Homer Ferguson Tells Propeller Club United States Cannot Maintain Position Without Strong Merchant Marine

WE have one thing at least in connection with the defeat of the recent shipping bill that we ought to be thankful for, said Homer L. Ferguson, president of the Newport News Shipbuilding and Dry Dock Company, in addressing a recent luncheon at the Propeller Club, and that is, that we don't have to listen any more to the opinions of Congressmen representing various sections of the country, and this also applies as well to editors of newspapers, including some of New York city's leading dailies, who know next to nothing about the problems of the shipping industry.

In speaking of the present situation, he pointed out that a large number of Shipping Board vessels should be sunk or scrapped. In fact, he declared that if they were operated they would surely break the company that tried to run them. The first thing to be done in stabilizing the present situation is to get rid of inefficient Government tonnage.

Mr. Ferguson spoke very earnestly and feelingly about our naval sea power and he hoped that the ten-year holiday would carry

with it a program for strengthening our merchant marine, for that must be done if the United States is to maintain her position. Whatever nation controls transportation will also control the politics and welfare of the world, he declared.

The time has not come when you can leave your business to others, said Mr. Ferguson, and in his opinion to scrap 11 battleships that cost over \$300,000,000 and then allow our chief competitor to build two more in order to catch up with us was an idiotic policy.

In speaking of constructive economic laws, Mr. Ferguson believed that we never again, in our time at least, would be able because of the strength of financial interests to pass an economic measure unless it had the support of both parties. In regard to shipping, he pointed out that all you had to do to find out why the shipping bill did not pass was to pick up a list of the directors of English shipping lines. The answer is that plenty of ships exist and the other fellow has got them.

Referring to the Jones Act, Mr. Ferguson declared that the clauses seeking co-operation with the railroads had never been enforced and railroad interests were arrayed against American shipping. The transportation Act, he said, which practically guarantees a 5½ percent return to the railroads on their net investment, may not be a subsidy but at least it is a very substantial aid.

SENATOR COPELAND TO SUPPORT SHIPPING

Senator Royal S. Copeland pledged his support to American shipping in every way that he could conscientiously. Senator Copeland said that the evidence of prosperity in any country was shown by its seaports and that unless the Government recognized all elements that make for prosperity good times could not be permanent. He did not believe that any country was pursuing a wise policy unless it made ample provision for its shipping and its seaports to secure the carriage of its products. The senator made a stirring plea along the lines recently advocated by Colonel Roosevelt, namely: that individual citizens inform themselves concerning the merits of public questions.

SHIPPING POLICY MUST BE NON-PARTISAN

Winthrop L. Marvin, vice-president and general manager of the American Steamship Owners' Association, said that any constructive shipping policy should have the support of both parties and our merchant marine as our Army and Navy must be made a non-partisan issue.

Personal

G. H. FROEBEL, formerly manager of the Houston, Texas, branch office of the Westinghouse Electric and Manufacturing Company, has been appointed manager of the marine sales department of the company, effective April 1 with headquarters at the East Pittsburgh works of the Westinghouse Company.

JOHN N. ROBINS, founder of the Robin Dry Dock and Repair Company, Brooklyn, N. Y., and for many years associated with William H. Todd, president of the Todd Shipyards Corporation, died on March 25 at his home in Greenwich, Conn., aged 71.

Cooperation of Shipping Industry Sought

Questionnaires Issued Relating to Best Means for Disposing of Government Fleet

THE committee of the Shipping Board, consisting of Commissioners Lissner, Thompson and Chamberlain, who were appointed to study and prepare details of a plan for transferring Government vessels to private ownership, issued invitations to the American Steamship Owners' Association, the United States Ship Operators' Association and the Council of American Shipbuilders to send committees to Washington during the last week in March.

The result of these conferences is not known at the time this is written but the main questions under consideration were as follows:

1. In your opinion could buyers be found for Shipping Board vessels who would give a guarantee to maintain those vessels upon a prescribed service, if the Board, in return for this guarantee, expressed the willingness to sell the ships in question at less than the world market price for similar tonnage?

2. Over what period of time do you believe it is practicable to require a guarantee of service?

3. What in your opinion should be the nature of this guarantee?

4. What in your opinion should be the Board's policy with regard to the sale of good tonnage which is not required for operation upon desirable trade routes, especially as to (a) sale to citizens, (b) sale to Aliens?

5. What in your opinion should be the Board's policy with regard to tonnage which is inferior in design, equipment or general condition?

6. To what extent and on what terms can capital be raised upon shipping in today's financial market, and what can be recommended to facilitate the financing of purchases from the Board?

American Ship and Commerce Corporation Makes Big Gain

THE consolidated income account of the American Ship and Commerce Corporation for 1922, after deducting fixed charges, shows a profit of \$1,790,610.39, as compared with \$1,045,084.46 for 1921, according to the annual report recently made public. The aggregate net income of the parent company and its subsidiaries was a profit of \$2,545,770.95, against a loss of \$711,445.38 for 1921, or an increase of about \$3,250,000.

The report shows a considerable decrease in the surplus account, from \$5,466,000 in 1921 to \$975,000 in 1922. This decline, it is explained, is due to the sale of seven cargo vessels, upon which there was a loss of \$2,111,000, and the adjustment of values of other ships to accord with market values.

The parent company received dividends of \$3,264,472 from its stock in the William Cramp & Sons Ship and Engine Building Company, which, it is understood, was utilized in the purchase of the new passenger steamers *Resolute* and *Reliance*. The report states that new loans of \$5,000,000 were made during the year to finance the purchase of these ships, which works out at the rate of about \$145 a gross ton.

"The betterment in the operation of the shipping companies was \$1,620,000 and in the shipbuilding and manufacturing approximately \$1,540,000. The improvement in the case of the shipping companies may be explained as follows:

"1. The sale of seven cargo vessels, after several months' idleness, resulted in materially reducing costs by the elimination of lay-up charges and depreciation.

"2. Reductions in the operating and up-keep expense of the entire fleet.

"3. The profitable showing made by the new first-class steamers *Resolute* and *Reliance*."

The report says that the industrial activities of the company, carried on largely through Cramp's, are proving profitable and are steadily increasing in volume and importance. At present all the manufacturing plants of the Cramp company and its subsidiaries are running at capacity and further expansion will be necessary.

R. H. M. Robinson, president of the American Ship and Commerce Corporation, states that the failure of the ship subsidy bill does not materially affect the company's prospects, as the *Reliance* and *Resolute* have been transferred to the Panama flag, and other plans have been made without counting upon government support. The outlook for shipping generally, he says, depends upon adjustment of the financial and economic difficulties in Europe.

Income of New York Shipbuilding Corporation Reduced

The depression in shipping, the limitation of armaments and cessation of construction for the Shipping Board resulted in a considerable decrease in the business of the New York Shipbuilding Corporation in 1922, according to the annual report made public last month.

Net income for the year was \$1,026,267, at the rate of about \$5 a share, as compared with \$1,996,559 in 1921 and \$2,395,402 in 1920. Dividends were paid at the rate of \$1.50 a share, as compared with \$4 a share in the previous two years. Surplus for the year amounted to \$726,267, which made the total surplus \$6,140,905, subject to Federal income taxes.

The gross income last year amounted to \$1,184,517, against \$4,899,671 in 1921. Nothing was charged to amortization of plant, as compared with \$1,943,386 for this purpose the previous year.

Ships Ordered in 1923

DURING the first quarter of 1923 contracts were placed in American shipyards for 85 vessels of various types, including two express passenger steamers for coastwise service, a 13,000-ton freighter for the Great Lakes, seven Diesel-engined craft, a number of tugs, two dredges for the government, and a large fleet of steel barges for inland waterways service.

The vessels ordered since the first of the year are as follows:

Two passenger steamships, 402 feet by 72 feet 6 inches, to Sparrow's Point Plant of Bethlehem Shipbuilding Corporation, Ltd. by Eastern Steamship Lines, Inc., Boston, Mass., price \$3,600,000.

Two fishing steamers, one 140 feet long and the other 135 feet long, to M. M. Davis & Son, Baltimore, Md.

Combination towboat and lighter, 90 feet by 20 feet, to Vineyard Shipbuilding Company, Milford, N. J., by Cuban-American Sugar Company.

Bulk freight steamship, 604 feet by 60 feet by 32 feet, to Toledo Shipbuilding Company, Toledo, O., by Reiss Steamship Company, Sheboygan, Wis.

Steam lumber schooner of 1,200,000 feet capacity to Peninsular Shipbuilding Company, Portland, Ore., by A. B. Johnson Lumber Company.

Maneuver boat to Midland Barge Company, Midland, Pa., by U. S. Engineer Office, Huntington, W. Va., price \$21,475.

Dipper dredge hull to Penn Bridge Company, Beaver Falls, Pa., by U. S. Engineer Office, Pittsburgh, Pa., price \$23,145.

Three steel deck barges to the Independent Bridge Company by U. S. Engineer Office, Pittsburgh, Pa., price \$40,000.

Self-propelled houseboat, 60 feet by 16 feet 4 inches, to George T. Johnson and Sons, Cambridge, Md., for Charles B. Bossett, Brooklyn, N. Y., price, \$25,000.

Eight steel barges, 140 feet by 25 feet by 11 feet, and one barge, 280 feet by 50 feet by 11 feet, to Alabama Dry Dock and Shipbuilding Company, Mobile, Ala., by the Tennessee Coal, Iron and Railway Company.

Two steel oil burning tugboats, 105 feet 9 inches by 24 feet by 12 feet 9 inches, to Tebo Yacht and Basin Company of Todd Shipyards Corporation, by Standard Transportation Company, New York.

Five steel barges to Green Bay Dry Dock Company, Green Bay, Wis., by U. S. Engineer Office, Milwaukee, Wis.

Two Diesel towboats, 63 feet by 14 feet, to Hildebrand Shipyards, Kingston, N. Y., by Transmarine Corporation, New York, price \$75,000.

Steel oil barge to Los Angeles Shipbuilding and Dry Dock Corporation, Los Angeles, Cal., by Associated Oil Company, price \$45,000.

Two Diesel ferry boats, 120 feet long, to St. Helen's Shipbuilding Company, St. Helens, Ore., by Long-Bell Lumber Company.

One tug, 58 feet, by 17 feet by 8 feet, to the Erie Basin Shipyard, Buffalo, N. Y., by the Niagara Ferry and Transportation Company.

Four steel barges to the Nashville Bridge Company, Nashville, Tenn., by U. S. Engineer Office, Florence, Ala.

Pipe line dredge, 175 feet by 50 feet by 8 feet, to the Charles Ward Engineering Works, Charleston, W. Va., by U. S. Engineer Office, Cincinnati, O., price \$275,000.

Fourteen steel barges, 100 feet by 25 feet by 5 feet, to the Penn Bridge Company, Beaver Falls, Pa., by U. S. Engineer Office, Nashville, Tenn., price, \$156,535.

Three steel barges, 80 feet by 26 feet by 5 feet, to the Riter-Conley Manufacturing Company, Pittsburgh, Pa., by U. S. Engineer Office, Huntington, W. Va., price, \$32,190.

Four steel dump scows, 144 feet by 37 feet by 11 feet 8 inches, to the Newport News Shipbuilding and Dry Dock Company, Newport News, Va., by U. S. Engineer Office, Philadelphia, Pa., price, \$190,000.

Two motorships to Great Lakes Engineering Works, Detroit, Mich., for Minnesota Atlantic Transit Company, Duluth, Minn.

One oil barge, 87 feet by 28 feet 4 inches by 8 feet, to the Noank Shipyard, Inc., Noank, Conn., by U. S. Engineer Office, Philadelphia, Pa., price, \$21,900.

Twenty steel barges to the American Bridge Company, Ambridge, Pa., by Pittsburgh Coal Company, Pittsburgh, Pa.

America Contract Goes to New York Navy Yard

THE reconditioning and conversion of the steamship *America* into a cabin and third-class liner is to be carried out by the New York Navy Yard. The decision to award the contract to the Navy Yard, according to reports, was due to a belief on the part of Shipping Board officials that all bids were too high and that this matter could be adjusted more expeditiously by giving the job to the Navy Yard on the cost basis. The board appears to be uncertain as to the amount of work it will authorize but it is by no means uncertain in its decision to return the *America* to its berth in time to meet her sailing date of June 2.

It is not clear why this contract could not have been adjusted just as satisfactorily at a guaranteed price with private repair plants. Certain it is that the total bids submitted, including the Navy Yard estimate, did not vary materially and surely not enough to guarantee that the price of the job on the cost basis would not exceed the bid of the lowest bidder—the Morse Dry Dock and Repair Company.

According to Mr. E. P. Morse, president of that company, the Shipping Board had no choice in calling for figures from the Navy Yard because there is a law specifying that when work done on a Government-owned or controlled vessel exceeds \$100,000 in cost the nearest available navy yard must have a chance to estimate. Notwithstanding this law, the award of the job to the Navy Yard brought immediate protests from individual plants on the ground that the Navy Yard had no overhead or capital charges to meet and still further that it was not fair to tax commercial enterprises so that the money could be used to undermine their business.

Idle American Seagoing Tonnage Shows Decrease

ONLY a little more than 10 per cent of privately-owned American ocean-going steam tonnage was unemployed on January 1, 1923, according to a summary statement issued recently by the American Steamship Owners' Association, 11 Broadway. On July 1, 1922, 15.7 per cent of American ocean-going steamships was unemployed; on January 1, 1922, 23.5 per cent was unemployed.

Idle privately-owned American steamers numbered only 92 of a total of 320,405 gross tons register on January 1, 1923, as compared with 124 of 522,567 tons on July 1, 1922, and 171 of 780,653 tons on January 1, 1922.

This present improvement in the business of American shipping, according to Winthrop L. Marvin, vice-president and general manager of the American Steamship Owners' Association, "is due mainly to improved business within the protected coastwise trade of the United States, including the intercoastal trade via the Panama Canal."

To Build Two Barges

SEALED proposals will be received at the United States Engineer Office, Galveston, Tex., until 2 P. M., April 16, 1923, for furnishing and delivering two 1,200-barrel steel barges complete, afloat at any port on the Gulf of Mexico accessible to a seagoing tug drawing 12 feet of water.

Intercoastal Services Still Rapidly Growing

Shows What American Shipping Can Accomplish Under Favorable Conditions

THE increased activity in the movement of cargoes in the intercoastal trade is the most marked development in the employment of ships under the United States flag, during the past year. The employment of privately owned ships in the trade with other countries, where keen competition makes economical operation imperative and where our ships are handicapped by high operating costs has rapidly decreased; so rapidly in fact that at the close of the last quarter of 1922 our privately owned cargo tonnage was represented in the foreign trade by only 119 vessels, of which 61 were engaged in trade with the West Indies and Caribbean countries. Of the balance engaged in overseas trade, 26 were vessels owned by the large industrial companies engaged principally in the transport of their own products. Thus it will be seen that our privately owned American vessels on whom the burden of competition with foreign carriers falls are represented by a meagre total of 32 vessels. Other than the vessels of the United States Shipping Board, our merchant marine in foreign service does not equal the fleet of one good-sized British company.

PRIVATE VESSELS SEEK INTERCOASTAL BERTHS

The vessels under private ownership have practically abandoned the hopeless task of competing with the more cheaply operated foreign fleets, and have turned to the protected traffic of our coastal waters, where the basis of operation cost is equal, and an opportunity is presented of making a profit through increased efficiency in fair competition. A survey of the intercoastal business for the last quarter of 1922, shows how rapidly commerce can be developed where American shipping is not throttled by the lower operating costs which prevail on the vessels of other nations.

Secret Oil Deal Suspected

SENATOR ROYAL S. COPELAND, in an address before the Propeller Club on March 23, declared that the private car of Harry F. Sinclair, head of the Sinclair Oil Company, stood on a siding at Three Rivers, New Mexico, for three days just before the tremendous oil deposits at Teapot Dome, Wyoming, were leased to the Mammoth Oil Company.

Three Rivers is the home of Albert B. Fall, former Secretary of the Interior, and it will be remembered that the Teapot Dome wells, formerly known as Naval Petroleum Reserve Number 3, were removed from the jurisdiction of the Navy Department to the Department of the Interior. The lease was signed on April 7, 1922, but not made public until April 14, 1922.

The State of Wyoming and Secretary Edwin Denby protested against the lease and Senator La Follette caused a senatorial investigation of the deal to be made. It is believed that the lease was made without competitive bids and Senator Copeland pointed out that it was significant that just before the lease was made Mr. Sinclair's private car was held on a siding at Three Rivers for three days. Senator Copeland said that he was not through with this Teapot Dome episode.

For the last three months of 1922 the total cargoes moving in intercoastal trade amounted to 1,227,612 long tons, of which 336,691 tons were oil cargoes in tankers. The movement in eastbound traffic from the Pacific to the Atlantic and Gulf ports, excluding the oil cargoes, amounted to 479,144 long tons, while the westbound movement from the Atlantic and Gulf to Pacific ports amounted to 411,777 long tons.

RAPID INCREASE IN OIL CARGOES

The rapid increase in the movement of oil cargoes from the West Coast to the Atlantic is worthy of special comment at this time. The mounting output of the California oil fields guarantee us against curtailment of supply in case any large percentage of productive wells in the Mexican fields should run to salt water. The total oil movement by ship from the West Coast amounted in the last quarter of 1922 to 335,191 long tons or about 2,300,000 barrels, an increase over the previous three months of approximately 1,000,000 barrels.

For the same quarter, our imports of oil from Mexico amounted to 4,102,000 long tons, or approximately 28,000,000 barrels, a decrease from the figures for the corresponding period of 1921 of 1,368,000 long tons or about 9,425,000 barrels. This decrease has practically been absorbed by the development of the California fields and a decided increase in the movement of tankers in intercoastal trade is noted.

The general growth of the intercoastal business has greatly increased the number of vessels employed, and new companies have entered the field with large, well-equipped vessels. There were 143 vessels of 1,356,584 deadweight tons employed during the last three months of 1922, as compared to 93 vessels of 912,570 deadweight tons employed during the previous quarter. The total sailings from Atlantic to Pacific ports during the quarter comprised 107 vessels of 1,047,743 deadweight tons while from the Pacific to the Atlantic 109 vessels of 1,036,744 tons deadweight departed, making a total number of sailings in the three months' business of 216 vessels and 2,084,487 tons deadweight.

Atlantic Coast Shipbuilders to Meet on May 14

THE annual meeting of the Atlantic Coast Shipbuilders' Association will be held in Philadelphia on Monday, May 14. This meeting, which will be attended by the executives from the shipyards and ship repair plants from all sections of the Atlantic and Gulf coasts, will be given over almost entirely to the serious problems confronting the shipbuilding industry.

It is known that several members have already found some very decided views on what should be done individually and collectively by the shipbuilders and others are requested to give immediate thought to the same subject.

Install Sperry Gyro-Compasses

Sperry gyro-compasses have recently been installed on Standard Oil Company of New Jersey tankers, *F. W. Weller*, *O. T. Waring* and *James McGee* and on the *Lillian Luckenbach* of the Luckenbach Line.

Annual Meeting of U. S. Chamber of Commerce in New York May 7-10

Transportation and European problems as they affect American business will be the general topics considered at the eleventh annual meeting of the Chamber of Commerce of the United States, which is to be held in New York, May 7 to 10. Grouped within the broader discussion will be a series of exchanges of views that should prove of real value to the forward looking men in the various lines of industry. A group session will be held for each cross-section of American business, including a foreign commerce group which will show the direct application of Europe's tangled affairs to American business.

British Shipping Exhibition

The annual British Shipping, Engineering and Machinery Exhibition will be held this year at Olympia, London, from August 31 to September 22.

TRADE PUBLICATIONS

DE LAVAL EQUIPMENT.—A manufacturing plant in which low pressure steam for process purposes is supplied from a turbine of special design is described in a profusely illustrated leaflet issued by the De Laval Steam Turbine Company, Trenton, N. J. This turbine operates automatically either as a straight condensing turbine, as a back pressure turbine, as a bleeder turbine, or as a mixed flow turbine or as a low pressure turbine, in such a manner as to maintain a balance between power requirements, low pressure steam requirements, hot water requirements, and the amount of power available from water power. This is accomplished by a third pressure controlled valve, in addition to the high pressure and low pressure valves ordinarily controlled by the steam governor in a mixed flow turbine. The utilization of exhaust steam for heating and process purposes, or the production of power as a by-product from steam used at low pressure, offers surprising economies, and this leaflet will therefore repay careful study by steam users in these times of high fuel costs.

PORTABLE TIMING DEVICE.—Accuracy of .1 in 60 seconds is attained in a portable timing device, described in Bulletin No. 46053, recently published by the General Electric Company. This device consists of an encased clock, to be used with a standardized clock as a means of secondary timing, to supplant the stop watch. The portable timing device has applications which enable its use with graphic instruments, measurements of angular velocities, and for indicating a definite time interval ranging from one second to any whole number of minutes. As illustrated in the Bulletin, the instrument consists of a clock, relays, and a gear train which by adjustment can be set to meet different demands of service. Power is supplied from a local flashlight type of battery. Errors as great as .4 second are frequently introduced through the use of stop watches, according to this Bulletin, which quotes from an article "The Limitations of Stop Watches," by A. L. Ellis. In addition to cutting the possibility of error down to .1 second, the portable timing device can be utilized for measurements ordinarily requiring a combination of instruments.

Coastwise Steamship Berkshire Launched

THE new coastwise steamship *Berkshire*, of the Merchants and Miners Transportation Company of Baltimore, was successfully launched at the yard of the Federal Shipbuilding Company on Saturday, March 17. The sponsor was Miss Mary Franklin Cromwell, daughter of Mr. W. K. Cromwell, of Baltimore, a director of the Merchants and Miners Transportation Company. The *Berkshire* is a sister ship of the *Alleghany*, which recently completed her sea trials and is about ready for delivery. Both

Contracts About to Be Awarded in Start of Norfolk Terminal Project Which Will Cost Several Millions

NORFOLK, VA. (Special)—Bids for bulkheading and dredging the Hardy tract on the inner harbor of Norfolk to pave the way for development of that 3,000-foot waterfront into a system of industries on the plan of the Bush terminal in New York, were opened this week and contract for the work will be awarded early next week, according to Colonel M. A. But-

ler, will be under construction in a short time and would be ready for business not later than January 1, 1924. He was not prepared to disclose the nature of the industries.

The entire project, which Colonel Butler said will eventually run into the millions, has been financed by a syndicate, of which George Norris, Philadelphia banker, is the principal member.

American Marine Association to Stage Spring Banquet at Waldorf-Astoria

THE American Marine Association will hold a spring get-together banquet at the Waldorf-Astoria Hotel, New York City, on the evening of May 3. Senator Royal S. Copeland, Captain William Stayton, president of the Baltimore Steamship Company; Mr. Joseph E. Sheedy, vice-president of the Emergency Fleet Corporation, and other prominent men in the marine field will deliver addresses at this gathering.

The American Marine Association, in addition to staging the annual Marine Exposition at the Grand Central Palace, is acting throughout the year as a chamber of commerce in the marine field. It is busily engaged in conjunction with the Department of Commerce and the Shipping Board in promoting standardization and simplification of shipbuilding and ship engineering parts, a movement which Secretary Hoover has successfully started in many other industries. The object of the banquet is to bring the maritime field together in closer contact and to develop suggestions that can be acted upon in building up our merchant marine.

Shipping Board Appoints Central Fleet Survey Committee

AFTER a conference with captains, naval architects and engineers, port engineers and caretakers of the laid-up fleet, the Shipping Board Committee on Survey, consisting of Vice-Chairman O'Connor and Commissioners Plummer and Benson, has appointed a central fleet survey committee to outline proceedings to be followed in making a complete survey of the Government-owned fleet. This committee consists of J. H. Philbin, manager of ship sales, chairman; J. E. Bailey, manager of the repair division at New York; James Swan, naval architect, division of ship sales, and A. Conti, consulting engineer, division of ship sales.

Upon the adoption of a plan of procedure the central fleet survey committee will act.

Double Acting Four Cycle Diesel Engines Ordered

BURMEISTER AND WAIN, LTD., of Copenhagen, Denmark, have received an order from the Swedish-American Line for two double acting, four cycle Diesel engines of 7,000 horsepower each to be installed in the company's new 560-foot passenger liner now building for the New York-Gothenberg service. Burmeister and Wain are now prepared to furnish this new type of engine in sizes ranging from 4,000 to 8,000 horsepower.

Charter Gas Engine Company Takes Over Mietz Oil Engine

THE Charter Gas Engine Company, Sterling, Ill., announces the purchase of the entire "MIETZ" oil engine (also known as "Mietz and Weiss") business, heretofore carried on at 128-138 Mott Street, and 430 East 19th Street, New York City, by the August Mietz Corporation and the Reliance Oil Engine Corporation. This effects a merger and consolidation, under one management, of two of the oldest internal combustion engines in the world.

New Merchants and Miners' Coastwise Liner Alleghany

ships will operate in the coastwise trade between Baltimore, Savannah and Jacksonville. These vessels have the following dimensions and characteristics:

Length overall	368 feet
Length between perpendiculars	350 feet
Beam, molded	52 feet
Displacement	7,000 tons
Passenger accommodations:	
First-class	205
Steerage	27
Speed at sea	12 knots
Engine	4 cylinder reciprocating
Boilers (four)	Scotch

These vessels have been designed particularly for comfortable travel at sea. Ample public spaces have been provided. Special features consist of many private baths with hot water connections; single berth rooms; facilities for handling all types of automobiles, including limousines and other types of closed cars; modern electric lifeboat handling devices, and many other features in add to the comfort and safety of the passengers.

It is hoped and expected that these vessels will be the forerunner of orders for additional ones from many other of the American coastwise companies, who really should begin to modernize their fleets, if they want to make them attractive to the traveling public.

Atlas-Imperial Engine Company Opens New York Office

The Atlas-Imperial Engine Company, of Oakland, Cal., builders of marine and stationary Diesel engines, announce the opening of offices and display rooms at 115 Broadway street, New York City.

New Ryerson Plant in Cincinnati

Joseph T. Ryerson & Son, Inc., Chicago, has purchased the plant, stock and goodwill of the Cincinnati Iron & Steel Company, Cincinnati, Ohio.

Marine Construction News of the Month

Ship Contracts—New Ship Concerns and Shipyard Improvements—Terminal Projects—Government Contracts

SHIPS AND SHIPBUILDING

Overhauling, Newport News, Va.—The Norwegian steamship Romsdalshorn has been taken to Newport News for repairs.

Schooner Repairs, Norfolk, Va.—The schooner West Hardaway was towed to Norfolk for repairs to be made by Harriss, McGill & Company.

Gunboat Repairs, Charleston, W. Va.—The gunboat Wheeling, for some time stationed at Key West, has been taken to the Charleston Navy Yard for repairs.

Hull and Boiler Repairs, Mobile, Ala.—The tug Marion was placed on the docks of the Alabama Dry Dock & Shipbuilding Company for hull, boiler and several minor repairs.

Overhauling, San Francisco, Cal.—The ship Star of Lapland, of the Alaska Packers' Association, has been placed on the ways of the General Engineering Company for overhauling.

Steamer Reconditioning, Norfolk, Va.—The Old Dominion Transportation Company is reported to be expending approximately \$400,000 in reconditioning two steamers for passenger service.

Painting Steamer, Etc., Baltimore, Md.—The excursion steamer Charles Macalester was placed on Woodall's drydock, Baltimore, recently, for painting and preparing for the summer business on the Potomac.

Overhauling, Oakland, Cal.—The contract for generally overhauling and making interior changes in the Pacific mail steamer President Wilson was awarded to the Moore Shipbuilding Company, to cost \$9,528.

Contract Awarded, Kearny, N. J.—The contract for reconditioning the steamship West Africa, allocated to the Bull Lines, has been awarded to the Federal Shipbuilding Company. Estimated expenditure, \$45,000.

Restepping Mast, Chester, Pa.—The Sun Shipbuilding Company received the contract for restepping of the foremast of the Nawsco steamship Washash, carried away while lifting a heavy reel of wire rope. Approximate cost of repairs, \$15,000.

Overhauling Contracts, Oakland, Cal.—The schooner Thistle was placed on the Hanlon Dry Dock and Shipbuilding Company's ways for overhauling, and the Associated Oil Company's bay carrier Midway for overhauling and installation of a new capstan.

Miscellaneous Repairs, Mobile, Ala.—The Alabama Dry Dock & Shipbuilding Company was awarded the work of docking the steamship Hugoton for examination, scraping and painting, drawing tail shaft for inspection and some boiler and machine work.

Overhauling, Baltimore, Md.—The steamer Emma Giles has been placed on the ways of the William E. Woodall & Company for overhauling for the summer Tolchester excursion season. The B. C. and A. steamer Joppa will follow her in dock for an overhauling.

Machinery and General Repairs, Mobile, Ala.—The Todd Shipyard and Dry Dock Company, Mobile, received the contract for making extensive machinery and general repairs to the Sinclair Oil Company's tank steamer W. L. Connelly. Approximate cost, \$40,000.

Extensive Repairs, Wilmington, N. C.—Diamond Steam Boat and Wrecking Company was awarded the contract to raise the sunken steamer Kingston, now resting in 30 feet of water in Cape Fear River. After being raised and securely fastened to barges she will be towed to the marine railway for extensive damage repairs.

General Repairs, San Francisco, Cal.—The Bethlehem Shipbuilding Company received the contract for overhauling, drydocking, cleaning, painting and performing general repairs on the E. R. Ritch & Company's tanker Broad Arrow. The bids were: Bethlehem, \$1,395; Moore's, \$1,285.

Steamer Reconditioning, Mobile, Ala.—The steamship Effingham has been placed on the docks of the Alabama Dry Dock & Shipbuilding Company to have her tail shaft drawn for inspection, cleaned and painted from keel to load line, to install zinc plates, renew rivets, and various other repairs.

General Repairs, Oakland, Cal.—The contract for general repairs to the United States Geodetic Survey steamer Discoverer has been awarded to the Hanlon Dry Dock and Shipbuilding Company. The following bids were submitted: Hanlon's, \$2,181; Moore's, \$2,243, and General Engineering, \$2,294.

Vessel Launched, Toledo, O.—The freighter Worrell Clarkson, building for the Kinsman Transit Company, Cleveland, was launched on March 17 by the Toledo Shipbuilding Company. The vessel is 600 feet overall length, 60 feet beam and 32 feet deep, and is to be delivered to her owners on April 15.

Launch Construction, Oakland, Cal.—The Crowley Launch Company, of San Francisco, has started the construction of four launch hulls, which will be equipped with 150-horsepower Diesel engines. The vessels will be sixty-four feet long, eighteen feet beam, and will have two fuel tanks for storage of 2,000 gallons.

Contract Awarded, Oakland, Cal.—The Moore Shipyard was awarded the contract for making changes in the Shipping Board steamer President Pierce. The following bids were received: Moore, \$9,854; General Engineering Company, \$12,340; United Engineering Company, \$12,472; and Bethlehem Shipbuilding Company, \$12,681.

Reconditioning, Baltimore, Md.—Steamers Santa Cecilia and Corvus, formerly of the Green Star Line and now of the Planet Steamship Corporation, have been awarded to the Maryland Dry Docks for reconditioning. The approximate expenditure for reconditioning the seven ships formerly of the Green Star Line will be \$100,000.

Low Bidder, Oakland, Cal.—The Crowley Shipyard was low bidder for general repairs to the steamer Susquehanna, work including voyage repairs, etc. Seven yards submitted tenders, which were: Crowley's, \$4,123; General Engineering, \$4,243; Bethlehem, \$4,828; Hanlon's, \$4,843; Moore's, \$4,882; United Engineering, \$5,385, and Main Iron Works, \$5,570.

Damage Repairs, Seattle, Wash.—The contract for making extensive repairs to the steamship Commercial Traveller, of the Moore & McCormick Steamship Company, of New York, has been awarded to the Todd Dry Docks, Inc., of Seattle. Twenty-five of the plates will be removed and replaced in addition to other repair work. Approximate expenditure, \$100,000.

Boiler Repairs, San Francisco, Cal.—The Crowley Shipyard was low bidder for making boiler repairs to the steamer Susquehanna. The following proposals were submitted: Crowley's, \$1,965; Smith & Scanlon, \$2,020; United Engineering, \$2,049; Bethlehem, \$2,270; Moore's, \$2,933; Hanlon's, \$2,940, and the General Engineering and Shipbuilding Company, \$2,949.

Diesel Engine Installation, Chester, Pa.—The Sun Shipbuilding Company, Chester, Pa., is installing Diesel engines in the following ships, recently bought from the Shipping Board: steel tanker Bidwell, 10,254 deadweight tons, 7,641 gross tons; steel tanker Miller County, 10,254 deadweight tons, 7,366 gross tons; and the steel cargo carrier Challenger, 11,850 deadweight tons, 7,955 gross tons.

Miscellaneous Repairs, Los Angeles, Cal.—The Los Angeles Shipbuilding and Dry Dock Corporation has been awarded the following contracts: Shipping Board tanker Tulsagas, machinery and hull repairs; Standard Oil tanker E. T. Bedford, machinery and hull repairs; Standard Oil tanker F. Q. Barstow, maintenance repairs; Standard Oil tanker Walter Jennings, extensive machinery and hull repairs; British tank steamer, the San Fraterno, drydocking and repairs.

Machinery Installation, Jacksonville, Fla.—Power suction pumps for use in supplying the dredges with boiler water are being installed on the U. S. E. D. tug Brannan, at the plant of Merrill-Stevens Company, Jacksonville. The machinery is intended primarily for use in operating the dredges in that district, but will also be adaptable for fire fighting. The intake suction pipe measures eight inches in diameter and there are several hose lines that can be played on flames.

Shipyard Work, West Coast.—The following contracts have been awarded to West Coast shipyards: Spreckles yacht Venitia and Mexican States Line steamer Colima to be drydocked for overhauling, cleaning and painting, to the Bethlehem Shipbuilding Corporation; steamer W. R. Chamberlin, Jr. installation of new booms and self-discharging and loading gear, to Hanlon Shipyards; and the cutter Pioneer and transport Buford for reconditioning, to the Moore Shipbuilding Company.

Reconditioning of Vessels, Oakland, Cal.—The Moore Shipbuilding Company will carry out reconditioning and repairs costing \$200,000 on the steamers Lake Frances and Lake Cayuga, recently purchased from the Shipping Board. The changes will include the installation of four masts, eight new booms, new winches, changing the fuel system from coal to oil, placing of new steel guards on vessels and other work. They will have an average speed of 10.05 knots and will be used as lumber carriers.

Ferry Launched, Staten Island, N. Y.—The new Staten Island ferryboat W. R. Hearst was successfully launched at Staten Island on March 17. She is equipped with 2,200 horsepower General Electric turbine generator, supplying 2,300 volts to the two induction motors, which are connected to the propellers. These motors have two speeds, 2,100 horsepower, at 176 revolutions per minute, used for driving the ferry and 100 shaft horsepower at 12 revolutions per minute, used to turn over the bow propeller.

Conversion to Oil Burner, Weems, Va.—Harpheys Railway, Inc., has been awarded the contract for the installation of oil burners in the E. H. Hubbard, Jr., of the Taft Fish Company. It is understood that this vessel is the first fishing schooner of a total of between 75 and 100 of such craft in the vicinity of Chesapeake Bay which are likely to undergo similar reconditioning. The boats are about 140 feet long by 18 feet beam, the propelling machinery developing about 750 indicated horsepower with steam supplied by a single-ended Scotch boiler with three furnaces.

SHIPYARDS AND DRY DOCK

New Drydock, New Orleans, La.—The ninth of chain of shipyards, operated by the Todd Shipyard Corporation, will be established in New Orleans within a few months, according to General Manager M. F. Hart. This will be a shipbuilding drydock and repair plant, involving an investment of \$3,000,000.

Drydock Sold, Portland, Ore.—The 2,000-ton drydock operated by the Columbia River Drydock, Engineering & Construction Company, of Portland, Ore., has been sold to J. L. McLain and Otis Cutting, of Seattle. The operation of the dock in Lou-

ering and raising a hull, it being a one-section type, its controlled by compressed air.

Drydock Sale, Boston, Mass.—According to announcement by Sidney Henry, Director of Sales of the Emergency Fleet Corporation, the Atlantic Works, Boston, Mass., has bought the 6,000-ton steel floating drydock, built by the Ramberg Drydock & Repair Company, and the purchaser expects to tow the dock from Brooklyn to Boston within the next few weeks. The Shipping Board still has five drydocks for sale, including three 10,000-ton wood floating drydocks located in New York harbor; one 10,000-ton wood floating drydock located near Providence, R. I., and one 6,000-ton wood floating drydock located at Jacksonville, Fla.

PORT IMPROVEMENTS

Harbor Improvements, Port Stanley, Ont.—Harbor of Port Stanley is to be improved. \$100,000.

Grain Elevator, Port Arthur, Ont.—J. Richardson & Sons, Royal Bank Building, Toronto, plan concrete addition to grain elevators, Port Arthur. \$500,000.

Pier, Sheboygan, Wis.—A pier is planned with docking facilities, hoisting and unloading machinery, etc., on Lake Michigan near South 8th street. J. Steimle, city clerk.

Wharf and Terminals, Corpus Christi, Tex.—Plans are being prepared for a wharf and terminals along Corpus Christi Harbor. Price, \$4,000,000. Sands & Cummings, Houston, engineers.

Drydock Machinery, Esquimaux, B. C.—R. C. Desrochers, Secretary, Department of Public Works, Ottawa, Ont., received bids on March 15 (change of date) for machinery for drydock at Esquimaux.

Grain Elevator, Norfolk, Va.—Norfolk Port Commission is having plans prepared for a gallery addition to grain elevator, Hampton Roads; price \$180,000. Folwell & Ahlskog, Sewells Point, architects.

Dredging, Etc., Houston, Tex.—Anderson, Clayton & Company, Mason Building, is taking bids for dredging channel for 600-foot wharves, concrete warehouses, etc. Price, \$1,000,000. W. L. Clayton, manager.

Terminal, Los Angeles, Cal.—Outer Harbor, Dock and Wharf Company (Union Oil Company, controlling interests) plans terminal wharves, docks, etc., on harbor front at Los Angeles. Cost, several million dollars.

Grain Elevator, Ft. William, Ont.—The Western Terminal Elevator Company awarded a contract to Eagles Construction Company, Ft. William, for reinforced-concrete addition to elevator. Engineer's estimate, \$500,000.

Grain Elevators, Port Arthur, Ont.—Gillespie Grain Company, 187 Grain Exchange Annex, Winnipeg, Man., are having plans prepared to rebuild and extend reinforced-concrete grain elevators at Port Arthur. \$800,000.

Bulkhead, Wildwood, N. J.—R. H. Coney, 106 East Garfield street, Wildwood, received the contract for constructing a bulkhead and for sandfill improvements on beach front from Schellenger to Montgomery avenues. Price, \$41,478.

Grain Elevator, Port Arthur, Ont.—Saskatchewan Co-operative Elevator Company, Regina, Sask., is having plans prepared for a reinforced-concrete addition to the port grain elevator; \$500,000. C. D. Towe & Company, Whalen Building, engineers.

Contract Awarded, Baltimore, Md.—The contract for dredging and making fill at McComas street bulkhead, 1,300,000 cubic yards, was awarded to Sanford & Brooks, Commerce and Water streets, and Arundel Corporation, Fidelity Building. Price, \$304,000.

Woodpile Wharf, Wilmington, Cal.—Pacific Coast Box Company, Central Building, Los Angeles, has had plans prepared by A. C. Martin, architect, Higgins Building, Los Angeles, for a 900-foot woodpile wharf, this being part of a \$1,000,000 improvement plan.

Levees, Etc., Yuba City, Cal.—Reclamation District 1550 has had plans prepared for reconstructing levees, enlarging canals, etc. Price to exceed \$500,000. J. Crowley, California Fruit Building, Sacramento, Cal.

Wharf, New Orleans, La.—Sealed proposals were received by the Board of Commissioners of the Port

of New Orleans, Suite 200, New Court Building, on March 22, for furnishing, erecting and painting of steel framing required for wharf structure at Poland Street Landing.

Dock, Superior, Wis.—The Great Northern Railway, Railway Building, St. Paul, Minn., plans to rebuild No. 1 ore dock at Allouez Bay, plans calling for reconstruction of inner 188 pockets and increasing height of dock from 73 to 77 feet, timber construction; \$1,500,000. R. Rudd, president.

Ferry Landings, Toronto, Ont.—City and Board of Harbor Commissioners, Harbor Building, are planning new ferry landings at foot of York street and at Toronto Island, \$26,000 and \$38,000, respectively. R. C. Harris, city engineer. E. L. Cousins, Harbor Building, engineer of Harbor Board.

Improvements, Palo Alto, Cal.—Plans are being prepared for the development of Mayfield Slough, 42-acre site, roadway on levee to landing, \$5,550; timber quay wall, 500 feet long, \$8,214; dredging channels, \$2,600; grading and graveling landing, \$2,750; warehouse, \$5,400, etc. J. F. Byxbee, Jr., city engineer.

Contract Awarded, Dallas, Tex.—The Jones Hettelslar Construction Company, 706 Mutual Building, Kansas City, Mo., received the contract awarded by the Pearlstone Mill & Elevator Company, Hickory street, for a reinforced-concrete addition to grain elevator, 200,000 bushels capacity. Price \$60,000.

Pier Construction, Charleston, S. C.—Engineers are preparing plans and specifications for the construction of a pier, costing \$150,000, to be built on property now occupied by piers Nos. 1 and 2 of the Union wharf at the foot of Market street, due to a suggestion to the Port Utilities Commission by Mayor John P. Grace.

Contract Awarded, Vancouver, B. C.—The Dominion Construction Company, Ltd., 509 Richards street, Vancouver, was awarded the contract for constructing a 700,000 bushel grain elevator, concrete storage house, timber work house and wharf on Burrard Inlet, by E. A. Woodward, Grain Exchange, Winnipeg, Man. Price \$500,000.

GOVERNMENT WORK

Boilers, Florence, Ala.—U. S. Engineer plans to purchase and install four steam boilers.

Harbor Dredging, Claibourne, Md.—U. S. Engineer plans dredging in Claibourne Harbor.

Piling, Louisville, Ky.—U. S. Engineer plans to purchase steel sheet piling for Dam 44, Ohio River.

Lock Gates, Nashville, Tenn.—U. S. Engineer plans steel lock gates for Lock S, Cumberland River.

Excavation, Wilmington, Del.—U. S. Engineer, Wilmington, plans dredging in Chesapeake and Delaware Canal.

Lock Gates, Chattanooga, Tenn.—U. S. Engineer will purchase lock gates for Widows Bar Lock and Dam.

Dredging, New York, N. Y.—U. S. Engineer, 2nd District, plans dredging and rock removal in New York and New Jersey Channel.

Dredging, Rouge River, Mich.—U. S. Engineer Office, Detroit, Mich., received sealed proposals on March 17 for dredging in Rouge River, Mich.

Wharf, Norfolk, Va.—Specification 4777.—Bureau of Yards and Docks, Navy Department, Washington, D. C., will soon take bids for extension to Wharf C, Norfolk.

Barges, Nashville, Tenn.—Penn Bridge Company, Beaver Falls, Pa., received the contract for fourteen steel barges for U. S. Engineer Office, Nashville. Price, \$150,535.

Removing Wreck, Buffalo, N. Y.—Sealed proposals were received on March 10 for removing wreck of steamer Arizona from St. Lawrence River at Cape Vincent, N. Y.

Survey Boat, Jacksonville, Fla.—The Burger Boat Company, Manitowoc, Wis., was awarded the contract by U. S. Engineer, Jacksonville, for one motor survey boat. Price, \$4,925.

Gates, Cincinnati, O.—Sealed proposals were received on March 28 by U. S. Engineer, Cincinnati, for furnishing, delivering and erecting gates for Locks 36, 38 and 44, Ohio River.

Dredging, New Orleans, La.—U. S. Engineer Office, New Orleans, will receive sealed proposals until April 9 for dredging Intracoastal Waterway between Bayou Black and Bayou Terrebonne, La.

Acetylene Cylinders, Staten Island, N. Y.—Sealed proposals were received by Superintendent of Lighthouses, Staten Island, on March 29, for furnishing 450 seamless drawn steel acetylene cylinders.

Dredging, Galveston, Tex.—The contract for dredging channels at Brazos Island Harbor was awarded by the U. S. Engineer, Galveston, to J. Jacobson, 2217 Avenue C, Galveston. \$181,200.

Dredging, Galveston, Tex.—U. S. Engineer awarded the contract for dredging 30-foot project in Houston Ship Channel to United Dredging Company, 233 Broadway, New York City, at a price of \$350,000.

Dredging, Honolulu, H. T.—U. S. Engineer awarded the contract for dredging in Honolulu Harbor, 1,250,000 cubic yards excavation, to Hawaiian Dredging Company, 854 Kuhuhuana street. Price \$949,540.

Castings, Etc., Florence, Ala.—U. S. Engineer, Florence, awarded the contract for furnishing castings and other parts for regulating gates of Wilson Dam to Charles Ward Engineering Works, Charleston, W. Va. \$119,300.

Painting, Repairs, Etc., Staten Island, N. Y.—Sealed proposals were received by the Superintendent of Lighthouses, 3rd District, Staten Island, on March 26, for docking, cleaning, painting and repairing the lighthouse tender Spruce.

Tanks, Florence, Ala.—The contract for furnishing displacement tanks for regulating gates of Wilson Dam was awarded to J. S. Schofield, Hammond and Boundary streets, Macon, Ga., by U. S. Engineer, Florence. Price \$136,300.

Dredging Ladder, Cincinnati, O.—U. S. Engineer, Custom House, Cincinnati, awarded the contract for a dredging ladder for 24-inch pipe line dredge to J. and J. B. Millholland Company, 714 Fifth avenue, Pittsburgh, Pa. Price, \$35,497.

Contract Awarded, Huntington, W. Va.—U. S. Engineer, Huntington, awarded the contract for constructing and delivering three steel barges to Riter-Conley Manufacturing Company, Leedsdale street, Pittsburgh, Pa. Price \$32,190.

Dredging and Rock Removal, Tampa Harbor, Fla.—Sealed proposals will be received by U. S. Engineer Office, Jacksonville, Fla., until 12 M., April 3, 1923, for dredging and rock removal in Tampa Harbor, Fla. Further information on application.

Lock Construction, Newburg, Ind.—U. S. Engineer Office, P. O. Box 72, Louisville, Ky., will receive sealed proposals until 2:00 P. M., central time, April 10, 1923, for constructing Lock No. 47, Ohio River, at Newburg, Ind. Further information on application.

Dredging Pump, Jacksonville, Fla.—United States Engineer Office, Jacksonville, Fla., will receive sealed proposals until 12 M., April 20, 1923, for furnishing and delivering a dredging pump for the United States dredge Barnard. Further information on application.

Dredging and Rock Removal, East River, N. Y.—Sealed proposals will be received by U. S. Engineer Office, Room 710, Army Building, 39 Whitehall street, New York, N. Y., for dredging and rock removal in East River, N. Y. Further information on application.

Painting Piers, Hoboken, N. J.—Bids were received at the office of Commissioner T. V. O'Connor, United States Shipping Board, 45 Broadway, New York City, on March 23, for the work of painting portions of Piers 1, 2 and 3, Shipping Board Terminal, Hoboken, N. J.

Manila Rope, Memphis, Tenn.—Sealed proposals will be received by Mississippi River Commission, 1st and 2nd Districts, Custom House, Memphis, until 11 A. M., April 3, 1923, for furnishing and delivering approximately 103,000 pounds of Manila rope. Further information on application.

Galvanized Wire, Etc., Memphis, Tenn.—Proposals were received at the office of the Mississippi River Commission, 1st and 2nd District, Custom House, Memphis, on March 26, for furnishing and delivering 870,000 pounds of galvanized wire, wire strand, and staples, and 24,000 wire rope clips.

Steel Sheet Piling, Louisville, Ky.—Sealed proposals will be received by U. S. Engineer Office, P. O. Box 72, Louisville, Ky., until 2 P. M., cen-

tral time, April 5, 1923, for furnishing and delivering steel sheet piling for Dam No. 44, Ohio River. Further information on application.

Motor Dredge Tender, San Francisco, Cal.—Sealed proposals will be received at U. S. Engineer Office, San Francisco, until 11 A. M., April 6, 1923, for constructing, testing and delivering ready for operation, one 40-foot motor dredge tender complete. Further information on application.

Concrete Wharf, Etc., New Orleans, La.—Sealed proposals will be received by the Board of Commissioners of the Port of New Orleans at their office, Suite 200, New Court Building, until 3 P. M., April 5, 1923, for concrete wharf, chain walls and column footings for shed at Claiborne Avenue Landing.

Dredging, Norfolk, Va.—Specification 4771.—Bureau of Yards and Docks, Navy Department, Washington, D. C., awarded the contract for dredging approximately 14,000 cubic yards at Navy Yard, Norfolk, to Norfolk Dredging Company, Campostella Wharf. \$0.395 per cubic yard, scow measurement (30 days).

Lock Construction, Ohio River.—Sealed proposals will be received by U. S. Engineer Office, P. O. Box 72, Louisville, Ky., until 2:00 P. M., central time, April 10, 1923, for constructing Lock No. 47, Ohio River, at Newburg, Ind. Further information on application.

Dredging, Astoria, Ore.—Specification 4615.—Bureau of Yards and Docks, Navy Department, Washington, D. C., awarded the contract for 400,000 cubic yards of dredging at the Naval Submarine and Destroyer Base, Astoria, to Gilpin Construction Company, foot of Fourteenth street, Astoria; price, \$0.15 per cubic yard.

Contracts Awarded, Huntington, W. Va.—U. S. Engineer, Huntington, awarded the following contracts for lock operating machinery, etc., for Dam 30, Ohio River: H. P. Gazzam Machine Company, 3200 Penn avenue, Pittsburgh, Pa., Lot A, \$7,995; J. & B. Milholland Company, 714 Fifth avenue, Pittsburgh, Pa., Lot C, \$6,739. Lots B and D rejected.

Structural Metal for Locks, Etc., Vicksburg, Miss.—U. S. Engineer Office, Drawer 421, Vicksburg, will receive bids until noon, April 7, 1923, for furnishing and delivering about 467,000 pounds of structural metal for locks and dams Nos. 5 and 8, Ouachita River, La. and Ark., and for erecting four steel gates at No. 5 and modifying two steel lock gates at No. 8. Information on application.

Dredging, Etc., Philadelphia, Pa.—Specification 4738 A and B.—Bureau of Yards and Docks, Navy Department, Washington, D. C., awarded the contracts for dredging, filling, wood bulkhead and concrete drain at Philadelphia, to American Dredging Company, 308 Chestnut street, \$0.33 per cubic yard; and to McLean Contracting Company, 1415 Fidelity Building, Baltimore, Md. (item 4a), \$14.945.

NEW INCORPORATIONS

The Pocahontas Steamship Company, capital \$500,000, incorporated under Delaware laws.

The Malston Company, capital \$800,000, to operate boats, incorporated under Delaware laws.

Universal Steamship Corporation, of Dover, Del., chartered under Delaware laws, capital \$100,000.

The American Export Corporation, of Manhattan, has increased its capitalization from \$25,000 to \$100,000.

The Colombian Steamship Company, of Wilmington, Del., capital \$1,800,000, chartered under Delaware laws.

The Olympus Steamship Corporation, of Manhattan, capital \$10,000, chartered at Albany. Incorporators: W. S. Auld, J. J. Binder and S. Brander.

The Algerian-American Shipping Company, capital \$50,000, chartered at Albany. Incorporators: George H. Haynor, Jr., E. Jones, and W. D. Greenlees.

The Superior Transportation Company, of Manhattan, capital \$50,000, chartered at Albany, to engage in the navigation business. Incorporators: L. J. Lake, J. E. Lee and A. M. Hull.

The Planet Line, of Manhattan, capital \$50,000, to engage in ocean commerce, incorporated under

New York laws. Incorporators: E. E. Baldwin, F. V. Barnes and R. F. Weeks, attorneys.

Daniel Ripley & Company, capital \$100,000, steamship company operating mainly out of Gulf of Mexico ports. The company has moved its headquarters from Galveston to Houston, Tex., a branch office to be maintained at the former port. Walter Terry Smith is president of the new corporation.

John J. Lenahan, of Buffalo, has just become associated with the Cowles Towing Company of that city, and the company has been incorporated under the name of Cowles Towing Line, Inc., capital \$50,000. The new company will take over the steel and wooden tugs, derrick boats, lighters and wrecking equipment of the Cowles company, a property valuation of about \$150,000. The business will be expanded. Operations will be in Buffalo harbor.

FOREIGN ACTIVITIES

Contract for Steam Colliers.—A contract for two steam colliers for Messrs. France, Fenwick and Company, Ltd., of London, has been secured by Messrs. Vickers, Ltd., of Barrow. The ships are to be 280 feet in length and to have a speed of ten knots.

Passenger Ship Launched.—A finely modeled twin screw steel passenger steamer for the British India Steam Navigation Company, Ltd., has been launched by Swan, Hunter & Wigham Richardson from their Neptune Shipyard, Newcastle-on-Tyne. This vessel, which is 440 feet in length and 55 feet 6 inches in breadth, will be propelled by two four crank triple expansion engines balanced on the Yarrow Schlick & Tweedy system. Steam will be supplied by 8 boilers working under Howden's system of forced draft.

Wear Yards Get New Contracts.—Five new orders for vessels have been recently placed on this river. An 8,000-ton vessel goes to Messrs. W. Pickersgill & Sons, another 8,000-ton ship goes to Messrs. J. Priestman & Co., two 3,300-ton vessels to Sir J. Laing & Sons, and a self-trimming collier of 1,800 tons to Messrs. J. Crown & Sons. Contracts for 40 new vessels have been placed on the Wear during the past few months and practically every shipyard on the river has work in hand.

Moore Line Steamer Launched.—The Orangemoor, fourth of the large steamers to be constructed for the Moore Line by the Northumberland Shipbuilding Company, has been successfully launched at their plant at Howdon-on-Tyne. This vessel is of the shelter deck type and will have a carrying capacity of 9,000 tons deadweight. Her principal dimensions are: Length, 415 feet; breadth, 53 feet; and molded depth, 35 feet 6 inches. The propelling machinery consists of a triple expansion engine built by the North Eastern Marine Engineering Company, Ltd., having cylinders of 27, 45 and 75 inches diameter, and a stroke of 48 inches.

WE GUARANTEE that of this issue, 4,700 copies were printed; that of these copies 3,829 were mailed to regular paid subscribers, 230 were provided for counter and news company sales, 215 were mailed to advertisers, 167 were mailed to employees and correspondents and 259 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 24,300—an average of 4,860 copies a month.

MARINE ENGINEERING AND SHIPPING AGE is a member of the Associated Business Papers, Inc. (A. B. P.), National Association of Periodical Publishers, Inc., New York Business Publishers' Association and the Audit Bureau of Circulation (A. B. C.).

Requests for change of address should reach us two weeks before the date of the issue with which it is to go into effect. It is difficult, and often impossible, to supply back numbers to replace those undelivered through failure to send advance notice. In sending us change of address, please be sure to send us your old address as well as the new one.

MARINE ENGINEERING AND SHIPPING AGE announces the removal of its office from the Woolworth Building to 30 Church Street, New York.

Economy and Efficiency

THIS issue of MARINE ENGINEERING AND SHIPPING AGE is devoted to economy and efficiency not only because a great opportunity for savings in the cost of operating our ships actually exists but also because there is no better way of convincing Congress and the people of the United States that a permanent and constructive shipping policy could be adopted than by the elimination of every practice that may be pointed out as wasteful.

When Mr. H. E. Brelsford, chief of the technical section of the Shipping Board, made the statement, in his address to the Propeller Club on April 19, that "marine engineering is twenty-five years behind stationary practice" he presented a serious indictment against the shipping industry. Whether or not he is correct as to the number of years, unfortunately it is only too true that we do not get anywhere near the efficiency in the engine rooms of our ships that is commonly attained in power plants ashore.

We all know this but what makes it so serious is the fact that, unlike a shore establishment, the cost of operating a ship per annum is far more than the total purchase price of

the vessel at the present market values. Mr. J. B. Smull, president of the Emergency Fleet Corporation, and one of our most expert ship operators, in his testimony before the House Committee on Appropriations in 1921 said that it had cost his firm \$48 per deadweight ton per year to operate cargo ships on very favorable trade routes, namely, from New York to Hull and from New York to Bristol.

On longer routes and with less efficient supervision this operating cost per annum might easily approach \$60 a deadweight ton; in fact, this is approximately the figure recorded in Professor Chapman's "Relative Economy of Steam and Motor Vessels" which appeared in our January issue. But what is more striking is the fact that after removing all fixed charges, the shipowner who purchases a vessel at \$30 a ton or less spends each year more than his original outlay for his ship on items, every one of which is directly influenced by economy and efficiency.

Such being the case, the natural question is why do not the shipowners modernize their methods and the equipment on their vessels? The answer to this, to a large extent, is the ultra-conservativeness of shipowners, which originated from the fact that reliability is far more important at sea than on shore.

We have no controversy with shipowners where reliability is concerned but there are many ways, and we say this with all due respect to shipowners who have been in the business for a long period of years, in which increased efficiency would also mean increased reliability. There are places where co-ordination would save large sums in one department even if they caused slight losses in another. The time has come when the successful shipowner must not be satisfied, as will be pointed out in an article appearing in the June issue of our magazine, with a ship that meets requirements; he must, in order to compete, be sure that his vessel *best* meets every condition in every department.

Trim the Insurance Costs

A DEFINITE percentage of the overhead may be reduced, if full care is given the details that enter into the cost of insurance. It is worth the effort. Bear in mind that the two fundamental considerations taken into account by underwriters are the record of the steamship line and the trade in which it is engaged. On this basis the insured may arrange his coverage advantageously and economically by watching the following arrangements: *Insure on an annual basis*, rather than by the trip. This will result in a saving of an average of twenty-five percent of the premium,

dependent upon the length of the voyage and the trade the vessel is engaged in. *Watch the values*; that is, the amounts insured. Why pay for more insurance than you could collect in event of loss? Take out only so much as represents the actual values. *Keep repairs up*. Thus losses are minimized; and, for that reason, your rating is improved with the underwriters and you will always receive the most advantageous rate quotations. *Maintain a good record as respects losses*. This is the most important thing of all. Good records mean low insurance rates. To this end experienced officers and crews should be employed and they should be kept strictly on the job. Every care should be exercised in loading and stowage. Do not allow trickery in log entries; underwriters have a way of discovering the falseness in ascribing the consequences of carelessness to "heavy weather." *Cheap insurance is false economy*. The claim-dodging underwriter and the insurer of questionable solvency are the worst possible dependencies.

What Else Can Be Done?

THE announcement of the administration plan to develop our merchant marine even if it becomes necessary for the Government to directly operate the ships ought to make it plain to the whole country and the world at large that the time for action has arrived. Ever since the armistice was signed, over five years ago, we have indulged in endless conferences which we must acknowledge have resulted in no settled policy that could command the enduring support of the nation.

We appear to be as much at sea as we were at the start. Our most prominent shipping men, while opposed to the principle of Government operation, can suggest no practical alternative that would be reasonably sure of attracting private capital into the shipping business. In the confusion of the moment, however, there is one fact that is clear and that is, that there can be no doubt but that Chairman Lasker himself regards Government ownership as "poison ivy in the garden of industry."

Therefore to understand the President's viewpoint it is necessary to emphasize the fact that we have been operating our Government owned vessels on a system that no sane business organization would consider for a moment. We refer to the "heads I win, tails you lose" MO4 agreement under which the Government not only pays all the expenses of operating the ships but commissions besides.

The President is not proposing to substitute Government for private ownership. There are practically no privately owned vessels in the foreign trade. What he is trying to do is to develop paying trade lines that would be attractive to private capital in place of the vicious system now in vogue which offers no inducement for the operators to purchase the vessels allocated to them.

With shipowners demanding a revision of the shipping laws and with Congress refusing to allow a constructive shipping bill to come to a vote, thereby throwing back on the Administration the responsibility for developing the merchant marine, what could a red blooded President do but let it be

known that the American flag will not be allowed to disappear from the seas?

If American interests will purchase and operate vessels, well and good, they will receive the co-operation of the Shipping Board; but, if not, the President is prepared to direct that trade routes be developed at whatever monetary loss is necessary. Probably, however, the losses would be less than under the present system.

We say this because we know that the Shipping Board has developed an organization that can and will tune up the engineering and maintenance of these vessels to a high efficiency. The opportunity for instituting great economy is there and will continue to be until advantage is taken of the methods common in land practice.

We believe, therefore, that with shipowners taking a stand that it is not practical for private interests to purchase vessels until the shipping laws are revised, trade has increased and a permanent Government policy adopted, the President is justified in dressing up the ships and consolidating them into shipping lines that will be attractive to private capital. His chief aim is to establish an American merchant marine, under private ownership, if possible; but, if not, under Government ownership as long as necessary.

New Passenger Motor Liners

THE number of orders that have been placed recently for large motor passenger liners has caused something of a sensation in European shipping circles. The United Steamship Company of New Zealand started the ball rolling with their 20,000-ton, 600-foot liner which is now making good headway on the Clyde, and in which four 3,250 brake horsepower Sulzer engines will be installed. The Rotterdam Lloyd followed with a 15,000-ton liner, 550 foot in length, in which two 3,500 brake horsepower Sulzer type motors will be fitted, the hull and engines to be built in Holland.

The Swedish-American Line then contracted for a 17,000-ton liner to be built by Armstrong Whitworth on the Tyne and equipped with two 6,750 brake horsepower Burmeister & Wain engines of an entirely new type. This is undoubtedly the most remarkable development since the first motorship was built. The power will be developed in six cylinders and the engines will be of the double-acting four-cycle design. Burmeister & Wain have always viewed the two-cycle type with disfavor and their solution of the problem of developing high powers is to retain the four-cycle principle but to make the engines double-acting. Needless to say, they have carried out a vast amount of experimental work before feeling that they are on sufficiently safe ground to proceed with the manufacture of an engine of such extremely large size.

British owners have just placed two orders with Harland & Wolff, for 17,000-ton motor liners, in which a somewhat unusual machinery arrangement will be adopted. There will be four engines of the standard four-cycle single-acting design, but the ship will be a twin screw vessel with two engines geared to each shaft.

It will thus be seen that the motor driven liner is making great headway in England and the development has certainly been more rapid than most people anticipated.

Lake Hull Insurance

IN anticipation of the new season on the Great Lakes there is much evidence of activity on the part of shipowners and operators, insurance men and industrialists generally. The capacity rush in steel and iron, together with the increased demand and hardening of prices for copper, mean a good business in the Lake ore-carrying trade. Grain should also move freely, and as the country's prosperity is near a peak-point there is likely to be a heavy movement in west-bound package freight. This insures activity for both hulls and cargoes, as a dull season entails the tying-up of vessels and a consequent heavy return-premium drain for lay-up returns. An increasing fleet is being developed for the carriage of automobiles from Detroit factories to the East. Lake hull underwriters have been in conference and have thoroughly discussed terms and conditions for the new season. It has been agreed to meet last year's basis, with the exception that no allowance be made for \$2,500 deductible average. As was done in the last lake season, all freighters under any flag will be written at not less than 3¾ percent, on a value of not less than \$70 per ton, and only under the American Lake Hull 1921 form. Any exceptions to these terms and conditions are to be referred to a special committee of five appointed for this purpose. It has also been agreed that where policies attach after August 1 and before October 1 an additional rate of ½ percent pro rata will be charged. For policies attaching after October 1 a pro rata of 1 percent additional is to be charged. The underwriters have also been studying the numerous constructive total losses on wooden hulls last fall, and it has been decided to support the efforts of the American Bureau of Shipping as regards improvement in these conditions this spring; and to this end no policies are to be issued on wooden vessels without the insertion of a warranty requiring the vessel's classification by the Bureau. The insurance companies fail to discern any prospect of a reduction in repair costs and replacement charges, in view of the steady mounting of prices for steel and labor.

Is the Brooklyn Navy Yard Efficient?

IF as we believe the *raison d'être* of a navy yard is to expeditiously and efficiently repair and condition naval vessels, then it would appear from the observation of several of the hundreds of men whose business, or hopes of getting business, on the *America* has taken them to the Brooklyn Navy Yard that the first class battleship *Arkansas* is practically awaiting her turn while the major part of the attention of the official naval staff is being devoted to a merchant vessel.

There is no question in regard to the efficiency of the naval officers. They are fully competent to handle most any engineering job but if their attention must be divided between reconditioning an ocean liner and a battleship—the most intricate machine in the world—one or the other is bound to suffer.

We understand that no proportion of the fixed charges on the taxpayer's investment in navy yards is included in the estimates submitted on merchant repair work but what about

the pay of the supervisory force in charge of such work? Is not the pay of naval officers provided for in an annual appropriation? If such is the case, and the navy yards intend to solicit outside work, is there any good reason why this appropriation should not be cut according to the proportion of such work obtained?

Due to the indifference and ultra pacific tendencies of the people in the interior, it is going to be a difficult matter to secure from Congress sufficient appropriations for the Navy or the merchant marine. Why make it still harder by giving some of our "hard boiled" Solons an opportunity to point out that a navy yard engaged in extensive reconditioning work ought to be able to pay its own way just the same as private shipyards.

More than this the employment of a large number of men in a navy yard on merchant work is apt to cause suspicion that there is a vote-getting object in view. The Navy Department will find out, if it continues to compete with private yards for reconditioning jobs, that Congress will surely estimate the value of such work in determining future appropriations.

A Change of Attitude

THAT the conservative attitude of American shipowners toward the adoption of the motorship is changing to one of approval and even of enthusiastic support is becoming apparent as the results obtained with this type of propulsion abroad and the attitude of foreign shipowners are becoming better known to American engineers by personal investigation and observation. This change of viewpoint is shown by the recent statements of Mr. A. S. Hebble, superintending engineer of the Southern Pacific Lines, upon his return from an extended visit to the largest manufacturers of Diesel engines in Great Britain and Europe. Not only was Mr. Hebble very favorably impressed with the progress that has been made in the development of Diesel engines abroad but he has expressed the opinion that the motorship has a marked advantage over the steamship and that it offers great possibilities for the American shipowner to compete in world trade.

For the shipowner who is not favored with a supply of cheap fuel and has to buy fuel in the open market, Mr. Hebble believes that the motorship will prove the most economical, particularly in the transatlantic and transpacific trades and in service between the United States and South America. Regarding the adoption of this type of propulsion for passenger ships he heartily endorses the progressive policy of the shipowners abroad who have recently placed orders for five motor passenger liners varying from 15,000 to 20,000 each and declares that the Diesel engine is ideal for passenger liners up to 25,000 tons and of 18 knots' speed. Mr. Hebble has a word of caution, however, for those who have recently been impressed by the claims of Diesel engine manufacturers that the cheaper grades of crude oil or "boiler" oil can be used successfully as fuel in Diesel engines. While it is true that such fuel can be burned in most Diesel engines, the effect of this practice on the cylinder liners, pistons and valves, is more or less disastrous and the consensus of opinion abroad is apparently opposed to its use.

American Marine Standards Committee Meets

Method of Organization Adopted and Administrative Committees Appointed—Technical Supervisory and Sub-Committees Will Be Established to Recommend Standards for Hull, Engineering and Operating Details

IN order that the marine industries in the United States may benefit by the establishment of recognized standards for hull, engineering and operating details and thereby reduce the cost of ship construction and operation, so that competition with foreign shipping may be on more equal terms, the general committee on standardization, recently formed by the American Marine Association has adopted a plan of organization which will enable it to establish standards in the marine field comparable with the work of similar committees in other lines of engineering effort, both here and abroad, but entirely independent of them.

TO BE KNOWN AS AMERICAN MARINE STANDARDS COMMITTEE

At the third meeting of the general committee, which was held in New York on April 17 with Captain R. D. Gatewood, U. S. N., as acting chairman, it was resolved that the standardization and simplified practice project in the marine field be carried on under the name of the "American Marine Standards Committee."

The purpose of the American Marine Standards Committee is in line with the movement inaugurated by Secretary Hoover of the Department of Commerce for standardizing products and simplifying practice in the industries in order to eliminate waste and reduce costs. The extension of this work to the marine industries was proposed by Secretary Hoover at the annual Marine Exposition in New York last November and was taken up by the American Marine Association with the support of the Department of Commerce and the United States Shipping Board Emergency Fleet Corporation.

In order to carry out the work expeditiously and economically, the committee has adopted the plan of organization shown in the accompanying chart (Fig. 1). The American Marine Standards Committee will act as the executive committee, all details and correspondence being carried out through the office of its secretary in the Division of Simplified Practice of the Department of Commerce in Washington.

The work of the organization will be administered primarily by three committees as follows:

- A—Organization, membership and finance.
- B—Constitution and rules.
- C—Publicity and relations.

The policies of these committees will be carried out by the secretary.

ADMINISTRATIVE COMMITTEES APPOINTED

The following were appointed as members of the three administrative committees:

Committee A: Col. E. A. Simmons, president, American Marine Association, chairman; Capt. C. A. McAllister, vice president, American Bureau of Shipping, vice chairman; Charles F.

Bailey, engineering director, Newport News Shipbuilding and Dry Dock Company; Hugo P. Frear, naval architect, Bethlehem Shipbuilding Corporation, Ltd., and E. H. Rigg, naval architect, New York Shipbuilding Corporation.

Committee B: William F. Gibbs, president, Gibbs Bros., chairman; E. H. Rigg, naval architect, New York Shipbuilding Corporation, vice chairman; Capt. John F. Milliken, secretary, Neptune Association; John W. Gray, Newport News Shipbuilding and Dry Dock Company, and Capt. C. A. McAllister, vice president, American Bureau of Shipping.

Fig. 1.—Chart Showing Organization of American Marine Standards Committee

Committee C: Capt. C. A. McAllister, vice president, American Bureau of Shipping, chairman; Capt. R. D. Gatewood, U. S. N., United States Shipping Board Emergency Fleet Corporation, vice chairman; Col. E. A. Simmons, president, American Marine Association; John W. Gray, Newport News Shipbuilding and Dry Dock Company, and Capt. John F. Milliken, secretary, Neptune Association.

TECHNICAL SUPERVISORY COMMITTEES

Through the committee on organization known as Committee A, three technical supervisory committees will be created as follows:

- I—Committee on Hull Details.
- II—Committee on Engineering Details.
- III—Committee on Ship Operating Details and Consumable Supplies.

Through each of these technical supervisory committees there will be formed a large number of subject committees which will be assigned the task of studying and formulating a standard for such specific items as will from time to time be designated by the executive committee, of which Mr. A. Bouillon has been appointed secretary.

The Government's Shipping Policy

American Merchant Marine Will Be Established and Maintained Even if the Government Is Forced to Operate the Ships

By Harold F. Lane*

WHETHER government operation of the ships, left on the government's hands as a heritage of the war, is to be the only policy which the administration at Washington will consider available as a result of the failure of the subsidy bill is still an open question. Both the President and the members of the Shipping Board are opposed to the adoption of such a policy, and have let it be known that such a course would be adopted only as a last resort. Further efforts are to be made to sell the ships but, if buyers do not come forward on terms regarded as acceptable by the board, it has been decided to go to direct government operation of the vessels for an indefinite period. Apparently neither the administration nor the board is very optimistic any longer as to the prospects of selling the ships on reasonable terms, and it has been decided that sales will not be made at "unjustifiable sacrifices." Chairman Lasker has also indicated that unless the shipowners and operators have been "bluffing" heretofore on the subject of the terms in which they would buy, he regards the chances of obtaining acceptable terms as rather slim. He also said he did not believe that they had been bluffing.

EXTENDED CONFERENCE HELD AT WHITE HOUSE

An extended conference on the subject was held by the President with the full membership of the Shipping Board at the White House on April 14, and a thorough discussion of the problems to be solved was had in the light of a report on the board's committee, which was making a special study of the questions of policy involved. After the conference it was announced in a White House statement that the board had unanimously agreed, with the President's concurrence, *"that the chief end to be sought is the establishment and maintenance of an American merchant marine,"* and that "with the failure of the subsidy act the board is confronted with the possession of a vast number of ships and the heavy losses under the existing plan of allocated operations under managing agents."

TO CONSOLIDATE FOREIGN TRADE LINES

In compliance with the shipping act, the statement concluded, the board will proceed at once to the consolidation of foreign trade lines, and then offer the sale of these lines and ships under the authorization of the law, conditional on a suitable guaranty of maintained service. "If such sales can not be made without unjustifiable sacrifice of the ships, then the government will proceed to direct government operation aggressively pursued. In short, there is unanimous agreement that the existing law contemplates and authorizes an adequate and maintained American merchant marine, and such a course will be followed as will fully guarantee it and contemplate its larger development." It is hoped that following the consolidation of the lines it will be possible to enter upon a sales campaign within 60 days.

WILL ASK CONGRESS TO AUTHORIZE NEW CONSTRUCTION

If continued government operation becomes inevitable, Congress will be asked at the next session to make an

appropriation not only to meet the annual deficit from operations but also to undertake a considerable expenditure for new ship construction to balance the present fleet. President Harding is proceeding on the assumption that in this way the responsibility for the future policy will be placed squarely upon Congress. If it is unwilling to appropriate enough to balance the fleet and maintain it there will be nothing else to do than to get out from under as speedily as possible. The losses of the Shipping Board from fleet operations have been reduced to about \$50,000,000 a year, as compared with about \$150,000,000 when the present board took charge. The number of managing agents was reduced, and their form of contract has been considerably revised, but, if it is found impossible to sell the ships, there will be a discontinuance of the managing agency agreements, which the board believes will still further reduce the losses.

During the month, while the President and Chairman Lasker were in Florida, the policy committee of the board, headed by Commissioner Meyer Lissner, has been giving close study to the problem of what should be done in connection with the government-owned ships, and conferences were held by the committee with representatives of the shipowners, the shipbuilding industry and the managing operators. The results of the conferences were later submitted to the entire board, and its views of the various perplexing problems that have arisen were laid before the President at the conference held within a week after his return to Washington from the South.

POSITION OF STEAMSHIP OWNERS

The position of the American Steamship Owners' Association was set forth in a letter from A. G. Smith, president, to Commissioner Lissner on March 26, after a conference with the committee of the association. The letter stated that the association regards it as fundamental that the Shipping Board and Emergency Fleet Corporation should retire from the business of operating ships and place the operation of the essential routes in the hands of private owners. The Shipping Board should immediately scrap such vessels as are inferior in design, equipment or condition, the association said, and it should offer its remaining vessels for sale to American citizens without restrictions and without discrimination between buyers.

SHIP OPERATORS' VIEW

A committee representing the United States Ship Operators' Association also conferred with the Shipping Board committee on March 28 to present the views of the managing agents who are operating government-owned vessels under what is known as the M O 4 agreement. They stated that those operating Shipping Board vessels are ambitious to become shipowners and look forward to the time when circumstances will permit them to purchase, but that they must face the economic fact that capital will not invest in ship securities until the profits are equal to and as reasonably sure as those in other lines of business. This committee was given to understand by the members of the Shipping Board that it was the intention of the board to discontinue the M O 4 system, apparently because there

*Washington correspondent.

is little stimulus under it for ambition to become a shipowner.

Another conference was held on March 29 with representatives of the shipbuilding industry. The shipbuilders expressed the opinion that only by giving preferential treatment to American shipping could it be made sufficiently attractive to warrant the expenditure of the considerable sum of money that would be required for the purchase and operation for a number of years of any large number of government ships. Homer L. Ferguson, president of the Newport News Shipbuilding and Dry Dock Company, advocated such matters as the bringing of the Philippine trade of the United States under the coastwise laws, reduced railroad rates on through shipments for export and import when carried on American flag ships and the abrogation of those portions of commercial treaties with foreign nations that prevent preferential treatment in tonnage taxes to American flag ships and preferential customs duties on imports in American vessels.

The Shipping Board had also issued a statement intended to make it clear that there is no prospect of Shipping Board ships being sold at less than world market prices for unrestricted service under any plan that the board has had under consideration. Studies had been made for offering ships on lines at a considerable reduction from world market prices in those cases where the purchasers will guarantee to maintain the services in foreign trade for a term of years, but it was stated that there was no intention of making reductions where there is no guarantee of the maintenance of the service to foreign ports and no reason at all why reductions should be made for the sale of vessels to be used in the protected coastwise trade, where foreign flag ships may not compete. The statement added that there was, therefore, no reason why shipowners should

hesitate to buy ships at the present time for unrestricted or coastwise or intercoastal operation because of any expectation that ships for such service would be sold at greatly reduced prices later on.

Leviathan Now Largest Ship in the World

THE *Leviathan* will start on her maiden voyage to Southampton and Cherbourg as a passenger ship under the American flag on July 4. This sailing of the largest most famous and most luxurious ship in the world on Independence Day is highly significant of America's determination, in spite of all handicaps, to develop a transatlantic service that will offer even better inducements in the way of luxury, convenience and comfort than can be obtained on any of the ships of our maritime rivals.

The *Leviathan* was the greatest and most famous of all transports during the war. She has taken nearly 13,000 troops at one sailing, which is by far the largest number ever carried by any ship. American workmen, engineers and architects have now made her the greatest of all passenger ships. Her gross tonnage is now 59,956 and she will carry 4,200 passengers in addition to a crew of 1,100.

The *Leviathan* is 950 feet 7 inches overall and 100 feet in breadth. The height from the bottom of her keel to the top of her smokestack is 184 feet. Steam will be generated in 46 express type watertube boilers which have been fitted to burn oil fuel. The propelling machinery consists of direct connected Parsons reaction turbines driving quadruple screws. The normal shaft horsepower is 66,000 which will develop a speed of 23 knots. However, the power plant is capable of turning out 100,000 shaft horsepower.

The *Leviathan*, the Largest Ship in the World, As She Will Look When She Sails From New York on July 4 on Her Maiden Voyage to Cherbourg and Southampton. The *Leviathan* Will Be Operated By The United States Lines and Will Be Commanded by Captain Herbert Hartley. She is 950 Feet Long with a Beam of 100 Feet and a Gross Tonnage of 59,956.

Situation Demands Reduction in Cost of Operation

Fuel Conservation Committee Setting Pace in Reducing Fuel Costs— Cooperation of All Departments Must Be Rigorously Carried Out

By "Old Scotch"

THERE are always two ways of doing things—hence for Americans to operate ships successfully, they must either get more revenue than they are now receiving, or else reduce the costs of operation which are now being paid. Perhaps a combination of the two will best fill the bill. From the present outlook, however, the chances of getting more revenue are not very propitious, if we may judge by the action of the senatorial heads of blocs, or block-heads, just as you may choose to consider them. As world conditions improve, as they eventually must, freight rates will undoubtedly pick up, but that is in the future, and money expected several months or years from now, does not pay crews nor keep the fires burning under the boilers right at his time.

There is one absolutely sure thing that we have to face, and that is that our shipowners must have their expenses of operation cut down at once, or there are going to be many more Yankee ships tied up to the wharves than there are at present. Tied-up ships mean idle crews, so it behooves everyone connected with ship operation to look at this situation seriously and begin economizing in the expenditures with which he is connected. The head of a household, when faced with domestic problems requiring retrenchment, is prone to begin cutting down his wife's allowance, while he goes merrily on smoking good cigars and patronizing bootleggers.

GREATEST SAVINGS POSSIBLE IN ENGINE DEPARTMENT

So each department of ship operation thinks that the other fellow should retrench and cut down his expenses, supinely copying the ostrich in that respect. The engine department controlling expenditures for fuel, lubricating oils, machinery repairs and engineer's supplies naturally is the greatest spender of money, and he who spends most is usually the one who should make the greatest savings.

The writer might modestly inject in the discussion at this point, that he is no new convert to economy in engine operation, as most of our readers will recall that he has been advocating reforms of this kind for over ten years in the columns of MARINE ENGINEERING AND SHIPPING AGE. He must also admit that during the past five or six years of profligacy in the operation of American ships, his advice has been little needed, as the waste which has taken place during this period of high returns from ocean freights has been most appalling. Within the past year the reformation has begun in earnest, and there are already indications of much better conditions.

FUEL CONSERVATION COMMITTEE

The United States Shipping Board, the largest single operator of ships in the world, has set the pace. This has been brought about largely through the influence of Vice-President Joseph E. Sheedy in charge of ship operations, who himself has been a sea-going engineer and knows intimately the

problems confronting the men on the ships. The organization of the Fuel Conservation Committee to take up the task of reducing the cost of oil and coal, the largest single expenditure connected with the ships, is directly due to Mr. Sheedy and this committee has shown results which amply warrant the prediction that its efforts will be crowned with success.

This effort was made none too soon, as since the committee began to function last August the contract costs of both fuel oil and coal have advanced nearly fifty percent. Through the hearty co-operation of the Bureau of Engineering of the

Navy the oil-burning school at the League Island Navy Yard, Philadelphia, has been made available for all American marine engineers, who may be sent there by the Fuel Conservation Committee. Its course of instruction is not confined to engineers on government owned ships, by any means, as all superintending and operating engineers who are American citizens are welcomed at this school of instruction.

Tangible evidences of the good which this school is accomplishing are getting more and more frequent. Fuel reductions of from ten to even thirty barrels of fuel oil per day are reported by the graduates of the school, and they give direct credit to the instruction which they received at League Island. The old idea that any one could burn oil efficiently under marine boilers is rapidly disappearing. The right methods are the only ones to use, and these can be obtained only from instructions by experts, who have made an intensive study of every phase of the art.

Such terms and abbreviations as viscosity, CO₂, Beaumé and B. T. U's now mean something finite in the minds of sea-going engineers who have received instructions laid down at the school, where heretofore they were largely dismissed from the thoughts of men actually in charge of firerooms as merely "highbrow stuff," which needed no attention from the "practical" man.

A knowledge of the proper "refractories" used for furnace linings, is productive of great economies both in amount of fuel used, and in voyage repairs. Heretofore marine engineers have been at the mercy of well meaning but ignorant brick-laying repair men, in selecting and applying proper refractory materials for the "ship's stomach." Both theoretical and practical instruction are given at the school to all students, and a few hours of close application under the direction of skilled instructors will make the ordinary marine engineer fully cognizant of the latest and best practices along that line.

ACCURATE PERFORMANCE RECORDS CALCULATED

In addition to the school, the technical staff working with the committee is busily engaged in collecting and analyzing data obtained from the logs of the operating vessels. The present fleet is divided into several distinct classes and types, such as the 535's, the 8,800-ton vessels, the Hog Island ships,

etc., which are grouped together and lend themselves quite readily to the tabulation of comparative performances. Standard fuel consumptions are assumed, which are readily obtainable on efficiently operated vessels, and comparisons are made on the basis of knots run per ton of fuel expended, the draft of water during each particular run being given due consideration.

On the best vessels of a type a number are showing efficiency ratings of over 100 percent, on the assumed basis. It is quite easy to pick out the "poor actors" when the type data is recorded on one sheet for all of the vessels coming under the particular category. There have been several vessels which showed as low as 65 percent efficiency, by this method of comparison, which otherwise would have been undetected except in the bills for fuel, which probably would have been accounted for by more or less general denomination of "bad actors" due to war construction.

PERSONAL INSTRUCTIONS GIVEN

In most instances of this kind special inspections are made of the personnel and machinery, and the principal faults quickly located. If bad performances have been due to inefficient personnel it is surprising how quickly results have been improved under instructions given by the special inspectors attached to the technical staff of the committee. Copies of all these relative performance sheets are placed in the hands of the chief engineers of all vessels in the list. This at once appeals to their pride of performance and due to the inherent human characteristic of rivalry, usually results in better performances in future runs. The whole tendency is towards improvement all along the line. If the best results are obtained by chief engineers who have attended the school of instruction, the less fortunate operating engineers immediately express a desire to have the benefits of the school given to them.

FURTHER LEAKS TO BE STOPPED

The committee realizes that its work has only just begun and is determined to investigate and make improvements in all the minor details of operation where losses of fuel can be checked. The proper setting of propeller pitches for the various types of vessels is being given intensive thought, so that this important matter will no longer be governed by the personal whims of would-be experts, as has been too often the case in the past.

Poorly constructed and inefficiently operated condensing apparatus is a fertile source of fuel loss, and will be taken up by the committee experts, as soon as conditions will permit. Inefficient and wasteful port operation of auxiliaries cause great losses of fuel, oftentimes on vessels which are very efficiently operated while underway at sea. Methods for minimizing these losses are now being studied, and remedial measures will be applied as rapidly as possible.

The committee has already prepared, and had posted in the engine rooms of all sea-going vessels, rules for the receiving and accounting for all quantities of fuel. This, together with greater care in the recording of expenditures at sea, will greatly aid the work of economizing, by providing more accurate data on which the results are recorded.

ALL DEPARTMENTS MUST COOPERATE

Summing up, the economizing of fuel is well started and good results may safely be predicted. But economies must be started and rigorously carried out in every other expenditure connected with ship operation. The deck department and the steward's department must lend a hand, and squeeze out every cent of unnecessary expenditure in every detail, no matter how comparatively insignificant they may appear. Ship repairs on American ships have been one of the greatest sources of waste, and, although considerable reductions have been made, there yet remain vast improvements to be accom-

plished. This subject will be given more intensive consideration by an expert in another article in a later issue.

AMERICA SHOULD LEAD IN NEW METHODS AND INVENTIONS

In addition to all these efforts towards economy, we must not forget that Americans have a habit of leading in new methods and inventions when they really put their brains to work in any great industry. Mark how easily the lead has been taken in the automotive industry when American capital and methods went at that game in an intensive way. In the ballad of the *Mary Gloster*, the dying shipowner probably best expressed the possibilities along that line of effort in the following verse:

I knew—I knew what was coming, when we bid on the
Byfleet's keel—

They piddled and piffled with iron. I'd given my orders for
steel!

Steel and the first expansions.

It paid, I tell you, it paid,

When we came with our nine knot freighters and collared the
long-run trade!

And they asked me how I did it, and I gave 'em the Scrip-
ture text,

You keep your light so shining

A little in front o' the next!

They copied all they could follow, but they couldn't copy
my mind,

And I left 'em sweating and stealing a year and a half
behind.

In the wild rush of creating our merchant marine fleet, all ideas of improvements over existing conditions were thrown ruthlessly aside in order to get out the ships in time for war demands. Now with plenty of time to devise new apparatus and methods we should be able to re-condition many of our existing ships and make them up to date in motive power and auxiliaries, so that as a whole they can be "a little in front o' the next," the "next" in this instance being the average ships of our competitors.

DIESEL-ELECTRIC DRIVE PROMISING

As new construction is demanded our best talents should be devoted to designing the most efficient ships afloat. While the Diesel engine is decidedly a foreign "step" ahead of us, and we have not kept up with their pace at all, the electric drive is distinctly American. The combination of Diesel generator and electric drive appears to be the most promising field of advancement in order to get ahead of the other fellow, and keep ahead of him. American design and methods of manufacture, if applied to this new field of propulsive power, ought to enable us to step out ahead of all competitors so far as fuel economy and operating efficiency are concerned.

IMPROVE CARGO HANDLING METHODS

American methods and ingenuity in handling cargoes is another direction wherein advancement can be made. The present cargo handling costs in American ports are far too excessive, while the methods used for handling cargoes on our own Great Lakes are not altogether applicable to cargoes handled along our seacoasts, there is still much that can be learned and adopted from our fresh water brethren, both in apparatus and systems employed.

We must not depend too largely on the mechanical means employed in shipping, as after all is said and done our success must be gained by the intelligent use of modern means. To that end a great deal of study and improvement must be made by the personnel in order to bring about the necessary advanced efficiency to enable us to hold our own in the fierce competition we must meet on the seas.

Economy in Steamship Operation and Management

**Aggregate of Losses Often Considered Trivial by Americans
Is Frequently Sufficient to Maintain Our Foreign Rivals**

By Robert F. Hand*

THE events which led to the defeat of the subsidy legislation clearly demonstrated that there can be no government relief for the shipping industry of this country until public opinion has been educated to the vital importance of a merchant marine. There is every indication that this will be a long and tedious process, while the recent decision of the Treasury Department that repairs made in foreign ports are subject to a 50 percent ad valorem duty renders the immediate situation more difficult and leaves little hope in the minds of men responsible for the operation of American ships.

However, our steamship owners are accustomed to discouragement and used to facing handicaps. They are already planning ways and means of meeting the situation and operating their vessels against the deadly competition of subsidized foreign tonnage.

It is evident that a solution can only be worked out through extraordinary efforts to increase the efficiency of management and operation with a resulting economy that will reduce our operating costs to a level close to that enjoyed by our foreign competitors. This is an ambitious program, but it has been said that the average American throws away enough to keep a foreigner, and there is no doubt that we have in the past been guilty of great extravagance in the operation of ships.

CONTACT WITH SHIPS' ENGINEERS ADVISED

This is particularly true in the Engineering Department. We have not given the operation of machinery the study and thought necessary to obtain the lowest possible operating costs, and we have also failed to establish close touch with our ships' engineers and encourage them to keep abreast of the latest and best engineering practice. In fact, we have been inclined to consider losses through faulty machinery operation too trivial for consideration, but we cannot neglect them henceforth, and it may be found that they represent a considerable part of the fuel bill.

Any economy in engineering must depend primarily upon close and intelligent supervision and this must be founded upon an adequate and well planned set of performance records in the central office, as it is only by this means that useful comparisons can be made and faulty operation readily detected. These records must be supported by careful observations and intelligent reports from the ships' personnel, and the American engineer is well qualified to handle this important phase of his duty if he is properly informed and the shore end of the work is well taken care of in competent hands.

SYSTEMATIC RECORDS WILL HELP

Many sources of economy will be uncovered by a close study of the engineering records of ships. A careful analysis of indicator cards and the temperatures and pressures carried throughout the plant, together with a careful check-up on the condition of auxiliary machinery will generally lead to considerable economy. It will also be found that a material saving will result from a special campaign against leaks

with a thorough study of the packing used throughout the plant, with a view of assuring the best possible selection of material in each case.

Large saving can be accomplished by organizing repair work on a periodical basis to fall concurrently with necessary boiler cleaning. This method offers the advantage of centralizing the work in those ports where the best supervision is obtained, and saves money by enabling contracts to be placed under competitive bids after specifications have been carefully prepared. A well worked out schedule for periodical repairs and boiler cleaning will, moreover, permit a thorough inspection system to be

The necessities of our present situation will demand a much more thorough investigation and study of combustion problems than has been accomplished in the past. Fuel oil combustion efficiency is seldom checked by scientific means, and there is no doubt that the present methods of oil burning, particularly in Scotch boilers, can be largely improved for economy. Steamship operators may find it advantageous to encourage wider interest in this important problem and to enlist the assistance of Government laboratories and test plants in experiments leading to greater economy in the burning of fuel oil.

established, which will in itself promote economy.

SUCCESSFUL COMPETITION REQUIRES QUICK TURN-AROUND

Both shore and ship organizations of American companies will have to be trained to appreciate the vital importance of rapid loading, discharging and dispatch if we are to compete successfully with foreign companies who are far ahead of us in turning vessels around in port. We have been inclined to attribute foreign superiority in this respect entirely to better dock facilities, but it will be found that the vital factors in quick turn-around are organization, co-operation and energy.

PURCHASE AND CARE OF STORES

Engine and deck stores offer a very profitable field for special efforts to attain economy, because American ships have been in the past extremely wasteful and unbusinesslike in their methods of handling stores. Great care should be used by all concerned with the ordering of material to assure that requisitions are reduced to the minimum requirements of necessity, and that specifications are carefully written in all cases so that the ship's storerooms are not cluttered with material for which there is no use, and which, besides representing a useless initial expense, involves a steady loss through rapid depreciation aboard ship.

Little attention has been paid in the past to the proper stowage and care of stores aboard ship. Mates and engineers who are responsible for storerooms should not only see that their material is properly stowed with every advantage for preservation, but should also keep a very careful check and

*Assistant Manager, Marine Department, Standard Oil Company of New Jersey.

inventory of stores on hand, for if this is not done waste and extravagance are bound to result.

When a large or even considerable fleet is operated, great economy will result from establishing a central warehouse from which all vessels are supplied. This not only offers the benefits of quantity purchasing and careful inspection of material, but presents the added advantage of permitting a close scrutiny of requisitions and the best possible assurance that excessive or uneconomical orders are not filled.

Steamship operators will find it economical to adopt a combined Specification and Stock Book which is a standardization of all stores and equipment required for the operation of the fleet. This book should indicate to all concerned what items are on the standard list of each department, and also furnish brief specifications for each item, sufficient to identify it and to assure that the article purchased and supplied is the identical article required.

Items for each department may be arranged in two general groups designated "Consumable" and "Equipment," the distinction being governed by the value of the individual item and the frequency with which it requires replacement. For convenient reference and record keeping the contents of each of the above groups should be subdivided according to their general character or use into a number of classes, briefly defined and listed under a classification index.

It is believed that this system of classifying and ordering stores will result in marked economy, and after it has been in operation for a considerable period in this form, the book may be made the basis of a ship's allowance system which will effect further economy and efficiency in storing vessels.

A happy ship is always an efficient ship and a crew is never content if the men are not well fed. Good feeding does not necessarily mean extravagant operation in the Steward's Department however. It is entirely possible to improve the quality of meals aboard ship and at the same time make large reductions in feeding costs. This is proven by the experience of our company, which reduced its feeding costs in half during the period from January, 1921, to the present time, and accomplished during the same period a marked improvement in the quality and service of food.

This gain in efficiency followed an intensive economy campaign in the hands of an energetic Supply Section head. The purchase of provisions was carefully organized to provide quality products at minimum prices and a very careful check, based on a standard feeding provision list, was made of stores used aboard ship. In addition close contact was established between the office and the personnel of the Steward's Department afloat, so that incapable men were gradually eliminated from the organization and the personnel were instructed and encouraged to make the efforts that produced better results with a saving of more than 50 percent in cost.

It must be realized that whatever measures are adopted, their ultimate success will depend upon the loyalty and ability with which they are supported by the ships' officers. Therefore, the most important phase of the work that American steamship operators have before them is the special effort that must be made to keep in close touch with the seagoing personnel in order to impress upon them the necessity of economy and to enlist their loyal co-operation in attaining it.

Situation Demands Reduction in Cost of Operation

(Continued from page 260)

Schools of instruction in all branches of ship operation should be started along similar lines to those employed at the fuel burning school in Philadelphia. Our deck officers need advanced training in their functions of handling and stowing cargoes and in conducting ship's business in foreign ports.

Already the officials of Columbia University are looking into this matter in connection with their summer courses in industrial training of all sorts. With a very little encouragement on the part of shipowners, such courses could be started and made of incalculable benefit to the advancement of our merchant marine aspirations. Knowledge of all the details of any business is, after all, the controlling factor in any business competition.

The deck and engineer officers in our merchant marine of

the future can no longer rest content with a superficial knowledge of the rudiments of their profession. It is the special knowledge of all the ramifications of their jobs which will enable them to obtain and retain employment. The ship owners' interests must be studied in every way, for if it is not profitable for Americans to operate our ships, none will be operated, and the thousands of really good men who are now earning their livelihoods from following the sea, will have to seek employment in other industries.

Everyone connected with American shipping must go into this contest in spirit as well as in work. We must have faith in our own efforts, for without faith and a spirit to conquer what seems overwhelming obstacles, we will meet defeat. It is not true Americanism to give up a task which seems insurmountable. If our forefathers had not the spirit to win, we would today be a dependent colony, and not the leading nation of the world.

Up and at it!

Ship Repairs Represent 13 Percent of Operating Costs—How Can This Item Be Reduced?

CAPTAIN R. D. GATEWOOD, Director of Maintenance and Repair, United States Shipping Board, suggests that a solution for this problem lies in creating a high morale among the crew, in closely checking the method of awarding repair contracts, in knowing the cost of repairs and in having an efficient port staff. He has written a special article for the June issue of MARINE ENGINEERING AND SHIPPING AGE "Efficient Repair Methods Adopted by the Shipping Board," in which he outlines what the Board has done to reduce repair costs.

In an article on "Economy in Ship Repairs" which will appear in the same issue, Robert W. Morrell, M.E., Marine Superintendent of the Tidewater Oil Company, outlines the maintenance problem confronting the independent operator. Mr. Morrell treats the subject of repair economy in its proper relation to the general scheme of successful steamship operation.

Towing Model in Experimental Tank at Washington Navy Yard

Savings Possible With Properly Designed Propellers

Considerations Affecting Propeller Efficiency—Smooth Blades Cut Down Ship's Operating Costs 3 Percent—Wake Gain and Thrust Deduction

By Rear-Admiral D. W. Taylor, U. S. N. (Retired)*

POSSIBLE propeller efficiency depends primarily not so much upon the propeller itself as upon the combination of power absorbed, speed and revolutions for which the propeller must be designed. There is one other feature, however, which should always be given great weight, although the eternal compromise here must be between first cost and economy in service. I refer to the material used for blades. If this is an alloy which can be made very smooth in the first place and retains its smoothness fairly well between dockings, there will be great economy over cast iron or cast steel.

A paper by McEntee in 1916, before the Society of Naval Architects and Marine Engineers, is very significant in this connection. He tested four 16-inch propellers: Two of bronze, one of cast iron and one of cast steel. One bronze propeller was polished all over; the other three, all cast in the same mold, were tested as cast. The smooth propeller showed a maximum efficiency of 72 percent; the other three ran very close together, their maximum efficiency averaging 63 percent.

SMOOTH PROPELLER BLADES SAVE 3 PERCENT OF SHIP'S OPERATING COST

In service, after a certain amount of corrosion and pitting on blades subject to it, it seems altogether likely that the above loss of 12½ percent would be increased as compared with smooth blades. The first cost of the latter blades will, of course, be greater, but if the cost of fuel used for propulsion is, say, 25 percent of operating expenses, and we save

12½ percent by the smooth blades, this saving will amount to some 3 percent of operating cost, and it will be nearly all net saving.

While considering this question of propeller friction, attention may be invited to the great loss of efficiency when propeller blades happen to harbor marine growth. This is more common with naval vessels, liable to make long stays in harbors where fouling is rapid, than with merchant vessels, but it is obvious from the experimental results quoted above that a very moderate fouling, hardly perceptible to the eye, will cause a notable loss of efficiency. McEntee investigated this matter also, and found that a very foul propeller might show an efficiency only 50 percent of one with smooth blades. The propeller blades on merchant vessels can hardly be cleaned by divers, as is frequently done on naval vessels, but, if some one will discover a suitable propeller blade material that not only does not corrode but does not foul, he would confer a boon upon owners of shipping.

While there is, of course, for every type of propeller one best design to meet a given set of conditions, it is possible to design any number of different propellers whose falling off of efficiency below the maximum possible is so small that no one would detect the difference in service. This is no doubt the reason for the prevalent belief that it is very hard to design an inefficient propeller. Nevertheless, it can be done, and when we consider our lack of information as to the actual conditions under which propellers operate, it is remarkable that it is not done more frequently.

As the result of hundreds of tests of model propellers the

*Former Chief Constructor, United State Navy.

results of which have been made public, we are in a position to determine very satisfactorily a propeller that would drive a phantom ship—a ship that would show the resistance of the actual ship but would not disturb the water in any way. When, however, we consider the combination of actual ship and propeller, we at once get into trouble. The ship interferes with the propeller, so that the latter is usually essentially less efficient than if the ship were not there.

WAKE GAIN

This is not a large loss, however. A propeller, particularly that of a single-screw vessel, is working in a current—nearly always a following current or wake—caused by the frictional drag and the streamline and wave disturbances of the ship. This affords a possible gain of efficiency, if we can design our propeller to take advantage of it, but it seriously modifies the propeller design. Consider, for instance, a propeller to absorb 1,000 shaft horsepower on a single-screw 10-knot vessel. If the wake is equivalent to a uniform following current having 25 percent of the speed of the ship (by no means an excessive amount), the speed of advance of the propeller with reference to the water in which it works is not 10 knots but $7\frac{1}{2}$ knots, requiring a larger propeller and a finer pitch than if the speed of advance were 10 knots.

THRUST DEDUCTION

Unfortunately, also, there is a third factor wherein the actual ship differs from the phantom ship. The propeller cannot develop thrust without developing a certain amount of suction upon the after part of the vessel, thus increasing its resistance. We usually express this as a percentage of the gross thrust. This loss, on the average, is not far from the gain from the wake. The hull efficiency, as it is called, being the resultant of the wake gain and the thrust deduction, is usually somewhere near unity—seldom as much as 10 percent below or much more than 10 percent above. Both the thrust deduction and the wake vary with the characteristics of the vessel and the propeller size and location, and the only method known at present of approximating to them with good accuracy is that of an experimental investigation using models of hull and propeller.

In fixing upon the power for a ship, in case we have no line upon these factors of thrust deduction and wake, we can assume that they neutralize one another, or make a small allowance as a factor of uncertainty, but when it comes to designing a propeller we cannot do this. A positive wake necessitates a larger propeller than if there were no wake, and the thrust deduction, meaning more power so far as the propeller is concerned, also requires an enlargement of the propeller if we are not to lose efficiency from excessive slip. Hence, as to the propeller, these factors do not neutralize, but reinforce each other.

In practice, the increase in power necessitated by the thrust deduction is usually taken care of in the estimate of the power which must be delivered to the propeller. Assuming the power of the propeller determined accurately, if we knew the wake fraction, or ratio between the speed of the following wake and the speed of the vessel, we could design our propeller as accurately as for the phantom ship. Unfortunately, during the forty years since R. E. Froude's masterly paper of 1883, which for the first time, I believe, brought to the attention of naval designers these factors of wake and thrust deduction, experimental investigation has not enabled us to predict accurately the wake which a given screw in a given location with reference to a given hull will experience. However, the model basins of the world are going more and more into this matter. The last meeting of the Society of Naval Architects and Marine Engineers had a notable contribution on the subject from Professor Bragg of the University of Michigan, and there is little doubt that our

present uncertainties in this connection will be resolved in a comparatively short time.

Fortunately, however, we can get along fairly well without exact knowledge of the wake factor. The important thing is to recognize the fact of its existence and not proceed with the design of propellers from model experiments as if our ships were phantom ships. This would result in propellers being too small, and the easiest way to spoil a propeller is to make it too small. Nearly fifty years ago the famous *Iris* showed that the propellers as fitted on that British man-of-war were too large, but times have changed and few of us nowadays have ever encountered a propeller that was too large.

HOW TO DETERMINE WAKE FRACTION

In order to design intelligently from the point of view of efficiency, making use of the enormous amount of experimental investigation of propellers that has been published, it is necessary to determine somehow the wake fraction to be allowed. Many designers do this by indirect methods. The best plan is to determine the wake fraction by experiment with a model of the actual ship, and the next best is to deduce it from analysis of an accurate trial of a ship closely resembling the one we are considering, with propeller similarly located. The latter requirement is very important, if we aim at minute accuracy. However, these methods are practicable in comparatively few cases. In 1910 I suggested the roughly approximate formulæ given below:

If w denote the wake fraction,
 V the speed of the vessel,
 V_A the speed of advance of the propeller,
 and b the block coefficient of the vessel,
 then speed of wake $= wV$
 $V_A = V(1-w)$
 $w = -.05 + .5b$ for single-screw vessels,
 $w = -.20 + .55b$ for twin-screw vessels.

The above are based upon investigations published by W. J. Luke in 1910. The latest investigations indicate that the single-screw formula above is liable to give values to w a little high, and that the prismatic or longitudinal coefficient is a little better primary variable from a scientific point of view than the block coefficient. But taking ships as they are, until we are able to devise formulæ taking account not only of the fullness of the vessel but of the size and position of the propeller, the above roughly approximate formulæ are near enough for the purpose of propeller design when the first and second methods referred to above are unavailable. Probably, on the average, we will come a little closer to the single-screw wakes by using

$$w = -.10 + .5b$$

In any case, we will find large wakes for full, low-speed ships. Failure to realize the fact that these large wakes actually exist is liable to deceive us as to the efficiencies we are getting out of propellers. If the propeller of a single-screw ship shows in service an apparent slip of, say, 10 percent, we are apt to regard it as good. But suppose a 10-knot ship with a 25 percent wake shows an apparent slip of 10 percent. The speed of the propeller is $10/.9 = 11.11$ knots. Then the apparent speed of slip is 1.11 knots. Adding the 2.5 knots of the wake, the true speed of slip is 3.61 knots, corresponding to a true slip of 0.325. In other words, the screw is working with a slip, not of 10 percent, but of $32\frac{1}{2}$ percent and any screw working with a real slip of $32\frac{1}{2}$ percent is wasting a lot of power.

IMPORTANCE OF REVOLUTIONS ON PROPELLER EFFICIENCY

There is one more or less controllable factor which has a major influence upon the possible efficiency of a screw propeller; that is the revolutions per minute. To survey this question, the results of systematic experiments with small propellers are of great value.

Fig. 1 shows in a boiled-down form the limitations of a family of three-bladed propellers, all of the same blade width and the same root thickness of blade and covering the practicable range of varying pitch ratios. It is adapted from Fig. 212 of "Speed and Power."

If P denote the shaft horsepower, or power absorbed by the propeller,
 VA its speed of advance,
 R its revolutions per minute,
and d its diameter in feet,

then, assuming Froud's law of comparison, we can deduce two dimensionless characteristics, as below:

Revolution characteristic = $C_R = R \sqrt{\frac{P}{VA^5}}$

Diameter characteristic = $C_d = d \sqrt{\frac{VA^3}{P}}$

These characteristics are independent of size, so from the results of experiments with the model propeller we can determine R , P and VA and, hence, C_R and C_d , for any slip.

The curve for maximum efficiency is simply a line drawn tangent to the successive curves of efficiency for varying pitch ratios, all plotted on the C_R base, and the C_d line giving diameter characteristics for the maximum efficiency is simply a line joining the corresponding values of C_d . Of

Fig. 1.—Relation Between Power, Revolutions, Speed of Advance of Propeller Through Water and Maximum Efficiency Possible for Propellers of Average Blade Width ¼ the Diameter and Maximum Blade Thickness 1/20 the Diameter

course the curves of Fig. 1 would be different for other blade widths and blade thicknesses, but these have comparatively small effect, the former in particular having much less influence than is usually ascribed to it. And, as a matter of fact, the efficiency of the propeller type to which Fig. 1 refers is about the best obtainable with propellers of uniform pitch and ogival blade section. The point is that the particular features of the curves of Fig. 1 are the same as any other family of propellers would show. Hence with fixed R , P and VA we fix C_R , and hence the maximum efficiency obtainable. We may easily choose a diameter and pitch ratio that will absorb the power with a smaller efficiency, but nothing we can do as to diameter and pitch ratio will give us a greater efficiency.

The outstanding feature of Fig. 1 for present purposes is that for values of C_R found in practice the maximum propeller efficiency possible falls off steadily with increase of C_R . When C_R equals 3.5, the propeller efficiency, then at an absolute maximum, may be 73.5 percent or 74 percent. Double C_R and make it 7, and we have lost some 3 points of efficiency, our new possible efficiency being 70 percent. Again double C_R , making it 14, and our possible efficiency drops to a little over 64 percent, that is, 9½ points below the efficiency possible when C_R equals 3.5. This is a loss of about 13 percent based on the absolute maximum of 73.5.

Now the only controllable factor subject to material vari-

ation which enters into C_R is R , the revolutions of the propeller. Hence, unless we increase the number of screws, the only way to keep C_R down is to keep the revolutions down. Unfortunately about every other factor in the situation impels us to keep the revolutions high. With high revolutions the propeller is smaller, while the engines are smaller, lighter and cheaper, and, frequently, as in turbine drive, more economical. Compromise between the conflicting considerations is necessary, but it should be made with full knowledge of what we are doing. For instance, by adopting high revolutions we may lose 5 percent of propeller economy. If we gain 5 percent of fuel economy, there is no net loss in operation, and we have a cheaper and lighter engine. If we gain no fuel economy, we have a net loss in operation of 5 percent of fuel cost, and it is hardly likely any saving of first cost would offset this perennial drain from fuel loss.

DIFFICULTIES INVOLVED IN DESIGN OF PROPELLER FOR
LARGE LOW-SPEED VESSEL

Table I illustrates the difficulties confronting the propeller designer in the case of large low-speed vessels. Vessel No. 1 is a 10,000-ton deadweight tanker, which on trial, loaded, showed a maximum speed of 12 knots. As far as propeller design is concerned, however, the diameter and pitch in Table I would have been the same for 10 knots, or any other speed lower than 12 knots, provided always the variation of the power was as the cube of the speed throughout the range of speeds considered.

This is very closely true in this case, from 10 to 12 knots. We see from Table I, in the first column, that vessel No. 1 cannot avoid a rather low propeller efficiency. The revolution characteristic, in fact, was so high that the diameter characteristic had to be arrived at by extending the curve of Fig. 1.

The second column shows what could be done, if, by enlarging the cylinder diameters or length of stroke, we develop the same power at 60 revolutions. If we enlarge the propeller to about 21½ feet, which is practicable for the draft of water, we would increase the possible propeller efficiency to 0.63 a gain of about 7 percent over the 0.56 value. As a matter of fact, the gain would be slightly greater, and the diameter would not increase as much as indicated in the second column of Table I.

Table I.—Applications to Fig. 1

Conditions actual or assumed	Vessel No. 1		Vessel No. 2	
	As Tried	Assumed Reduced Revolutions	Twin Screw Actual	Single Screw Assumed
Speed of vessels in knots.....(V)	12	12	12.5	12.5
Revolutions per minute.....(R)	83.5	60	115	115
Shaft horsepower.....(P)	2,852	2,852	1,700	3,400
Block coefficient.....	0.801	0.801	0.75	0.75
Estimated wake fraction.....	0.30	0.30	0.20	0.20
Speed of advance(VA)	8.4	8.4	10	10
$R \sqrt{\frac{P}{VA^5}}$ (C_R)	21.8	15.6	15.0	27.8
Maximum propeller efficiency (Fig. 1)	0.59	0.63	0.634	0.56 about
C_d for same (Fig. 1)	8.13	9.80	10.03	
Pitch ratio for same..... (Fig. 1)	0.87	0.94	0.95	
$d \sqrt{\frac{VA^3}{P}}$	2.19	2.19	1.30	
Propeller diameter from above.....	17.5	21.6	13.0	
Pitch ratio from above.....	15.2	20.3	12.4	

This gives us only a first approximation. For a second approximation we would make P only 0.93 of 2,852, and C_R would be reduced to a little over 15. Vessel No. 1 actually had a four-bladed propeller of a type slightly different from the type of three-bladed propeller to which Fig. 1 applies, but the effect of change of revolutions upon effi-

ciency would be substantially the same. The apparent slip on trial was about 5 percent only, but for a wake fraction of 0.30 the actual slip would be 0.34, a different thing.

Vessel No. 2 is a large twin-screw motorship. With increasing confidence in oil engines, there is a desire to fit single screws instead of twin screws on motorships. Table I shows that in this case there would be a very serious loss of efficiency by doing this.

The cases in Table I are fairly typical, and the large low-speed cargo vessel is usually fated from the first to have a low propeller efficiency. One line of amelioration would be the adoption of a type of propeller adapted to give a higher efficiency at large values of CR than the standard type to which Fig. 1 refers. I believe a thorough investigation would show a possible gain of at least 5 percent for CR values of 20 or thereabouts. Even so, the efficiency would be less for large than for small values of CR , and lower revolutions would always result in a gain in propeller efficiency.

In the above, I have taken no account of cavitation. That is a special trouble where the law of comparison upon which Fig. 1 is based fails because the motion around the full-sized propeller differs from that around the model. Fortunately, for vessels where economy is a prime consideration, the conditions are seldom such as to involve danger of cavitation. This is a trouble of the extremely high-speed vessel.

THREE-BLADED PROPELLER SLIGHTLY MORE EFFICIENT THAN FOUR-BLADED

It may be remarked, in conclusion, that there is one matter affecting efficiency where the practice of naval and merchant ship designers seems widely at variance. I refer to the number of blades used. Broadly speaking, naval practice is to use three-bladed propellers, merchant practice is to use four-bladed propellers. Model experiments indicate a small but distinct superiority, as regards efficiency, for three-bladed screws. The difference is so small, however—not over 3- or 4 percent—that it would be hard to demonstrate on full-sized ships except by most careful and rather expensive experiments. For my part, I believe that such experiments would bear out the model experiments and show a slight advantage as regards efficiency for the three-bladed propeller. Of course there are other factors involved, as where conditions require the minimum possible diameter. In such cases the four-bladed propeller might be slightly superior.

Important Advance in Pump Valves Decreases Cost of Pumping

USERS and prospective users of pumps will be interested to know that some decidedly valuable improvements in pump valve construction are now announced by the Worthington Pump and Machinery Corporation, of New York. An entirely different form of valve has

Fig. 1

Fig. 2

been perfected which, when applied to service conditions that have been difficult for the older standard valves by causing them to cut and to leak, will eliminate both difficulties. It therefore increases the average pump efficiency; decreases the cost of pumping; and continually maintains the capacity of the pump at its maximum point.

After many years of building and operating pumps, the Worthington engineers have found that the principal cause of leakage is traceable to the excessive wear on the rubber, which while negligible in some cases is often quite bad. Thus Fig. 3 shows a photograph of a hard rubber valve after three months of a particularly hard service. Cracks and cuts caused by the valve seat and by the radiating ribs are plainly visible. Fig. 4 shows a medium rubber valve, also after three months of unusually difficult service. It is plain that the only way positively to prevent leakage with such ordinary valves in this condition is to remove and replace them with new valves.

To overcome this rapid and costly wearing, cutting and cracking action, the Worthington engineers have evolved the

Fig. 3

Fig. 4

new and novel type of valve shown in Fig. 2, known as the Worthington "Seal" valve for use when the conditions are too hard for the ordinary form of valves now in standard use.

This new "Seal" valve assures absolute tightness when closed, the manufacturers claim, because the rubber used is "flexible" and will always seat perfectly both at the hub and outer rim, its inner and outer seats, and so keep tight. Age and continuous usage do not cut grooves or cause cracks as has been demonstrated in the case of a flexible rubber seal used for one year in this new type of valve. At the end of the year there was no visible wear, there was no leakage, renewal was of course unnecessary and there was no cost for repairs.

The ingenuity and simplicity of this valve are evident upon inspecting Fig. 2. There are no screws, no bolts, no rubber rings, no nuts, no bushings, no rotating elements. The special new feature that makes this valve so good for hard service is the so-called "bottom plate." This is in effect a middle seat for the rubber valve proper. When the valve is closed this middle seat carries the entire load and prevents the rubber seal from cutting on the seats or ribs. This bottom plate moves up and down with the rubber, and so not only acts as a middle seat, but this middle seat is movable with the rubber and helps to keep the rubber valve in shape even when open. Thus all mechanical functions requiring strength and wear resistance are cared for by metal parts. The flexible rubber acts only as a seal against leakage.

All moving parts are light but made amply rigid. The lightness assures a smooth, quiet-running pump. The rigidity prevents the distortion that results in leakage.

It is not anticipated that repairs or replacements will be often required but the construction makes this easy when it does become necessary, and the cost of any possible repairs will be low because of the simplicity and inexpensiveness of all parts.

Efficiency Depends on Accurate Performance Records

Great Advantage in Knowing What a Vessel Is Capable of Accomplishing and Giving the Personnel a Mark to Shoot At

By C. J. Jefferson*

THE fundamental rule of sound business success is an accurate and true knowledge of production, selling and distribution costs for that business.

Temporary combinations of events may apparently disprove this axiom and while these circumstances exist, business success will occur in spite of the lack of this necessary primary knowledge. Then when the affairs of the world tend to restore themselves to normalcy, or perhaps sub-normalcy, the temporary period of success is broken down and due to the lack of the basic cost data, the problem instead of being met with good keen business judgment is treated with a wild hysteria which generally succeeds in completely demolishing the one time successful business.

It is this lack of cost data and an intelligent analysis of the various items that make up the basic cost which has resulted so disastrously to the numerous shipping companies that sprang up during the war time emergency when cost principles were ignored. It is this same lack of cost data which perhaps in a lesser degree makes the problem of the American merchant marine today so intangible and so subject to panicky attacks from both its friends and enemies.

There is, however, any number of good reasons why these basic costs have not been established. First of all, we have been willing to accept the statement that it costs more money to run our ships than it does for those operated under foreign flags and therefore instead of establishing a selling price by the true though more difficult method of first determining the basic cost, we have let our competitors set our sales price for us and we have endeavored to meet it.

This is not good business nor can a business established on this foundation carry on itself when outside help is withdrawn. The problem of establishing the basic cost is complicated, for the shipping business is subject to more variables, and each of these variables has a more definite effect than is the case in any other business.

The basic cost can be divided into five main divisions:

1. Maintenance and depreciation of equipment.
2. Insurance.
3. Cost of soliciting cargo.
4. Stevedoring.
5. Operation.

All of these divisions are more or less interlaced and yet each heading must be analyzed by people who are qualified in their particular phase of the question and their findings must be co-ordinated by a single head who shall establish the proper co-efficient for each value and unite the findings into a basic cost.

It is not possible in such an article as this to go into the details of organization or the necessary tabulations that must be made in each of these divisions in order that reasonably correct values can be established. In fact, the various routes of trade, the various types of cargo and service make it impossible to cover the entire merchant marine field with any one definite program of attack.

FORM FOR COLLECTION OF OPERATING DATA PREPARED

The force of the above statement has been made very evident to the writer in his work in the United States Shipping Board's Fuel Conservation Section, in establishing the

standards of performance for the United States Shipping Board vessels operating in different routes of trade. The chief difficulty has been to get the available data regarding the performance of engine department of the various vessels in such standard form that it could be compared to the performance of sister ships and in turn make possible comparison of one class with another, at the same time making due allowance for the various variables such as efficiency of personnel, efficiency of material, weather conditions, drafts and speeds, bottom conditions, ocean currents and numerous other variables. To this end the accompanying form has been drawn up and is now used. On this form, the operating data for the entire voyage are collected in a compact form suitable for analysis and comparison.

Sheet No. 1 contains the characteristics of the vessel under analysis, also a brief statement of the physical condition of the vessel on arrival at the termination of the voyage. This being made out by an inspector who boards the vessel as soon as possible after she has docked, and in some cases the vessel is boarded at Quarantine when he rides her up to the dock.

The ratings of the engineer officers as to "mechanical ability," "discipline," and "efficiency," are based on the observation, both of the men and the condition of the equipment of the department as well as an analysis of the performance throughout the voyage. This means intelligent analysis of their work list abroad and at home, careful inspection of the department to determine whether the equipment is functioning properly and is not simply well painted, that bilges and tank tops as well as floor plates are clean, that dangerous fire hazards due to fuel leaks and oil-covered tank tops and bilges are eliminated.

In fact it means an inspection and an analysis of actual conditions made by a careful and efficient engineer who will not be influenced by the personality of the operating force.

HOW RATINGS ARE ESTIMATED

The ratings given for personnel are based on general performance of the engine department crew. This is partially based on observation by the inspector, but must largely be made up according to their report of performance as given by their engineer officers. The equipment rating is based on observation and the operation rating is based on analysis of the physical condition and also on the efficiency of performance of the vessel for the entire voyage.

On a small chart on the bottom of Sheet No. 1 is roughly plotted the voyage so that the route can be seen at a glance. This is useful in cataloging the reports for comparative purposes.

Sheet No. 2 of this report is made up of a number of columns. Each column is given over to the different passages of the voyage. In case there are a greater number of passages than can be tabulated on this single sheet, any number of such sheets may be added to cover the entire voyage. These columns contain data which cover the major variables which will be met in operation and enable the person who is making an analysis of the voyage to locate the weak points of operation and make such recommendations as are necessary to improve conditions and build up the efficiency of operation.

The fuel performance is broken down into several factors such as fuel per twenty-four hours, miles per ton of fuel,

Fig. 3.—Chart for Determining Horsepower of Reciprocating Engines

fuel per horsepower hour during steaming period at sea. The fuel per horsepower hour factor, while one of the most important is one most difficult to obtain accurately and must therefore be used very guardedly.

In the case of turbine-driven vessels, the shaft horsepower factor is determined from the horsepower curves of the turbine and the average logged revolutions per minute, initial steam pressure, vacuum, and number of nozzles used for this determination.

In the case of reciprocating engines, actual cards are worked out. Then from the measured cut-off, initial pressure and back pressure taken from these same cards, the horsepower is computed, using the curves shown on Fig. 3. The relation of the actual to the theoretical horsepower gives the card factor. Then from the logged high pressure cut-off, high pressure chest pressure, the revolutions per minute and the vacuum or low pressure back pressure, and using the above mentioned back pressure, the indicated horsepower for each passage is computed.

PORT CONSUMPTION

The fuel consumed in port, both at anchor and in moving from dock to pilot station, and from pilot station to dock is tabulated so that an excellent sea performance may be checked and shown not to have been made at the expense of excessive port consumption. The efficiency of performance is based on the ratio of actual miles per ton of fuel to the standardized values. The methods of obtaining these standardized values has been explained in previous articles in this publication.

In determining these standards, this form of voyage report has been found most useful and by continuing to check the standards with these reports, the standards will be gradually revised so that they take care of a greater number of variables than was possible at the time they were originally drawn up. It is felt that this voyage report form when used by competent and experienced engineers will give the data for the engine department operation in such a form that the co-ordinator can set his co-efficient on this phase of the basic cost with a reasonable degree of certainty.

In addition to this, however, it will be necessary to handle the other phases in as thorough a manner and when the merchant marine business is subjected to this type of scrutiny, then will it be able to establish a sound business foundation which will enable it to meet fluctuating markets, crises in the affairs of the world's trade, peak loads and depressions, and still carry on its business in a safe, sane and sensible manner. When those times arrive which are so apt to arrive in any business, when the life of the business hangs on the decision of the moneyed powers or even the Government itself, as to whether or not it be given aid, then the facts of the case, through reliable back cost figures can be so presented that a just and fair decision can be rendered, help given and remedy applied so that the business can continue to function, then will the merchant marine be a reliable business which other big business systems will support.

Appendix

METHOD OF USING RECIPROCATING ENGINE HORSEPOWER CURVES

Having determined the value of R_a (see Fig. 3) read upward in vertical line P_1 curve which corresponds to the absolute initial pressure or absolute pressure in high pressure steam chest. At the point this vertical line intersects the P curve carry over on a horizontal line and read the mean referred pressure (with complete vacuum) value, which is the mean referred pressure on basis of absolute vacuum in low pressure cylinder.

This mean referred pressure (with complete vacuum) value is transformed into Mean Referred Pressure or M.R.P. by subtracting the back pressure (P_b) in low pressure cylinder.

Modern Boiler Room Economies

By J. J. Nelis*

MARINE engineers are naturally conservative, and the boiler being the heart of the power plant, in fact of the ship, they have been reluctant to make any changes that might cause operating delays. As a result of this there has been little, if any, change in marine boiler practice for a great number of years except a small increase in pressure and for certain large powers the adoption of the watertube boiler.

During the last few years land plants, where economy is paramount and reliability a secondary consideration due to their usually having spare boilers installed, a great number of vital changes as regards economy have been tried out and carried to a successful conclusion, so that these new devices are now standard practice.

CHANGES IN LAND BOILER PRACTICE

The three most important changes in land boiler room practice have been:

1. The adoption of better combustion methods, such as stokers and increased furnace volume. Neither of these have been found advantageous on ships to date, but are one of the possible future developments that will slowly but surely take place, particularly when the present era of oil fuel is passed, and most of the merchant ships are again using coal for fuel.

2. Another main change has been the adoption of superheaters which add to the amount of heating surface passed over by the hot gasses, thereby increasing the overall boiler economy, and also transfer to the steam heat units which increase the steam economy of prime movers and therefore the overall power plant efficiency.

3. The third main change has been the installation of economizers to add as nearly as possible all of the sensible heat to the water in a separate chamber where it can be more efficiently accomplished, and leaving to the boiler only the work of adding the latent heat of evaporation which is a duty that should be done by the boiler, and not, as at present in marine practice, using the boiler as a combined economizer and steam generator.

In present day practice, with a typical Scotch boiler installation using Howden or similar heaters to absorb some of the heat of waste gasses, the average boiler room economy, hand fired with coal, is about 60 percent of the total heat of the fuel. With a similar installation, using oil as fuel, an economy of not over 65 to 70 percent of the heat of the fuel is an average condition.

MEANS OF INCREASING BOILER EFFICIENCY

As against present day practice, it is possible in marine power plants at a relatively small cost, to add superheaters and economizers, giving an overall efficiency of not less than 85 percent of the heat in the fuel, which will closely approximate the economy found in large central stations ashore.

The above is based on using the present equipment aboard ships. It is possible when building new ships to arrange for a considerable increase in furnace volume, and also in steam pressure. The latter, however, will require new types of prime movers but, if installed and intelligently operated, will place the American merchant marine ahead of all its competitors as regards the economy of its boiler room and complete propelling equipment.

The new inner harbor-navigation canal at New Orleans, La., which has been built by the Board of Commissioners of the Port of New Orleans, an agency of the State of Louisiana, at an expense of \$20,000,000, will be formally opened on May 5. This canal connects the Mississippi river with Lake Pontchartrain.

How to Get a Shaft Horsepower Hour for All Purposes with Steam on from 0.75 to 1.00 Pound of Oil

By W. C. Watson and John Thomas*

No appreciable departure from established marine practice has been made in the form of propulsion discussed in this article. The authors have had in mind primarily reconditioning work, retaining in many cases the same boilers, some of the original auxiliaries and adding superheaters. But the turbine electric apparatus described lends itself to the introduction into marine practice of many of the important features that have been developed in connection with large power houses on shore, such as, for instance, the adoption of high steam pressures and temperatures, as well as advanced systems of feed water heating and auxiliary layouts, including evaporators.

THE development of turbine electric drive for ships has been so rapid during the last few years, that many are unaware of the results that can be obtained with this form of propulsion and the contribution it can make to the American merchant marine in establishing it on a sound, economical and competitive basis.

At a time when so many ships must be reconditioned before they are competitive, careful consideration should be given to the possibilities of this form of propulsion.

The turbine can be designed in its simplest form. Reversing elements are eliminated, as reversal of the ship is accomplished by a simple change in electrical connections. The generator to which the turbine is directly connected is practically identical in design with the type employed in large power stations, and which has proven itself reliable twenty-four hours per day for years. The motor is direct connected to the propeller shaft and is of the steel mill type. The entire equipment is controlled by apparatus successfully demonstrated, particularly in steel mill and electric railway service, on shore.

PROPELLING EQUIPMENT

The propulsion equipment involves simple rotation, no rubbing surfaces other than journal bearings, and the power delivered to the propeller is transmitted across an air gap of considerable proportions, which is, for all practical purposes, an elastic medium, thus eliminating shocks and excessive stresses imposed upon the apparatus from the propeller and the elasticity of the ship's structure.

Figs. 3, 4 and 5 show rotors of the turbine, generator and motor respectively, and give a good idea of the rugged construction of the major rotating parts comprising complete electric drive equipment for a single screw ship. For the ordinary twin screw vessel there would be two turbine generators and two motors. In any turbine electric drive equipment the weight of the major rotating parts represents only about 30 percent of the total weight of the machines.

Figs. 6, 7 and 8 show complete propulsion turbine generator, motor and control apparatus. The principal electrical currents are generated in stationary parts, which affords the simplest and most reliable cable arrangements between generators and motors. The component parts of large elec-

trical machines are by necessity mechanically strong, which introduces the highly desirable quality of maximum reliability into machines of this type.

Enough experience has been obtained during the last ten years with electrically driven ships to enable us to say that the cost of maintenance of this form of ship propulsion machinery is much less than that of any other type. Experience of large operators of reciprocating engine machinery indicates

that the average cost of upkeep is several dollars per shaft horsepower per year, whereas experience with electrically driven vessels, such as the *Eclipse*, *Jupiter* and Coast Guard cutters, indicates that the cost is practically nil.

A ship maneuvers with turbine electric machinery much as it does with reciprocating engines, except that the turbine generator is not reversed, which greatly simplifies maneuvering and lessens wear and tear on the

machinery. The efficiency is the same in the reverse direction as in the forward, also 100 percent power is available for astern operation.

COMPARATIVE WEIGHTS

In comparison with electric drive for small cargo vessels requiring from, say, 2,500 to 4,000 horsepower, the geared turbine is somewhat lighter. However, in the larger powers in the case of ordinary passenger and cargo boats, when it becomes necessary to break up the turbine into two or more units per propeller shaft, and the extra piping, cross over connections and oiling system are taken into consideration, the weight of electric drive is approximately the same as that of the geared turbines.

In some of the large liners the geared turbine installations are much heavier than equivalent turbine electric installations. In practically every case the turbine electric drive is about one-half the weight of reciprocating engines.

INCREASED FIRST COST JUSTIFIED

As far as the costs are concerned, turbine electric drive is somewhat more expensive than geared turbines for ordinary vessels requiring from 2,000 to 4,000 horsepower per screw, but when the added reliability, low cost of upkeep and superior maneuvering ability, as well as excellent economy and flexibility of arrangement, are taken into consideration the increased first cost is justified in many cases. For vessels requiring above 4,000 shaft horsepower per screw there is very

In considering any form of propulsion reliability is the most important factor. In electric drive, we have apparatus which has successfully demonstrated itself for many years in the solution of difficult mechanical problems encountered on land and sea. No apparatus can be supplied to ships with as few changes from highly developed land practice as that comprising turbine electric drive.

*Engineers with the Marine Department, General Electric Company, Schenectady, N. Y.

Fig. 4.—Propulsion Generator Rotor

Fig. 5.—Propulsion Motor Rotor

little difference in first cost between turbine electric drive and geared turbine drive, except in the case of certain passenger liners where electric drive would cost considerably less than geared turbines now used.

Aside from the advantages already mentioned, the special contribution which electric drive can make to the solution of the ship operators' problem is dependent upon two special

characteristics in which it is unique; first, the ease with which operating conditions can be measured and recorded, and, second, the ease with which the favorable conditions can be arrived at and controlled. The advantages of the first are not always frankly conceded. It has been said that the same

steam into the main condenser. Again evaporators are not included in these calculations. Table II shows the arrangement of the machinery.

In the analysis of both single screw and twin screw vessels the small turbine generators used for light, power and excitation will operate condensing under the same steam conditions as the main turbine, and at sea will normally exhaust into the main condenser, a small auxiliary condenser being provided for port and emergency use.

Electric Auxiliaries An Economic Necessity

Lines Along Which Our Efforts Must Be Expended to Minimize the Fuel Bills, Machinery Maintenance and Cost of Handling Cargo

By Walter Thau*

EVERY industry of any standing today has gone through a transition, forced by the necessity for lower costs, better and more uniform product and increased production. Of all the factors participating in these industrial revolutions, electricity stands indisputably first. Without electricity, the results could not have been obtained. Similarly, the ship must undergo a change, which is forced by the necessity for reduced operating cost and general economic improvements. Fortunately the movement has already received the impetus, and is successfully launched. The aggressive shipping interests already realize that great improvements in methods and performance are available by the use of electrical apparatus, and their interest in the situation is manifested today by a definitely increasing activity which is always a good indication of the outcome. Electricity will do for the ship what it has done for the steel mill, the mine, the logging camp, the textile mill, the rubber mill, the cement mill, and hundreds of varied manufacturing establishments.

Naturally enough the arrival of the motorship was almost simultaneously accompanied by the adoption of electrical auxiliaries. The builders of motorships soon recognized the waste encountered by the use of the donkey boiler and steam auxiliaries, and changed over to the all-electrical auxiliary system. This latter practice is in vogue almost universally today, a fact which furnishes sufficient proof of the suitability

of electrical ship auxiliaries, as well as the resulting economies effected by their use. The motorship, which in itself constitutes a tremendously important step toward economy, therefore set, or at least hastened, the pace toward the ultimate answer in the economical operation of ships, even though their first installations of electric auxiliaries were considered somewhat in the light of a necessity. The performance of the electrical auxiliaries on motorships during the last 10 or 12 years has proven and thoroughly established their reliability for the service.

In the case of steamships, however, the conditions are somewhat different. Here there is plenty of steam producing means available, and, with few exceptions, practice has doggedly adhered to steam auxiliaries. This practice is deserving of some sympathy, however, even though the justification for it is not apparent. The attendants knew no other than steam machinery, and for the most part the equipment was built and supplied by the shipyards whose machine shop constituted no small proportion of the total plant. However, this is no time for accepting passive consideration of electrical auxiliaries, even on steamships. The future American competitive ship will be the ship equipped with electrical auxiliaries, regardless of its type of propelling equipment.

ECONOMY IN FUEL CONSUMPTION

The improved fuel economy of electrically driven machinery is due entirely to the great efficiency with which electricity can be generated, transmitted and used. The in-

*General engineer, Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.

Installation of a flexible centralized generating plant makes it possible to convert the stored energy in fuel into a useful form of energy with the least expenditure of labor and with minimum losses. The transmission of electrical energy entails less loss of power than the transmission of energy in any other practical form. Furthermore, there are no losses in the electrical transmission systems when no power is being transmitted, which is a very important item when compared with the steam systems in which the condensation and leakage losses assume a considerable proportion, especially in cold climates. In the case of steam deck auxiliaries, the pipe line losses may easily amount to 25 percent in many cases. As a user of power, the electric motor supplied with energy from a central plant is in a class by itself, especially when compared with the donkey engine. These considerations are particularly important, in the case of deck machinery, steering gears and any machinery not located close to the boilers.

For existing ships, we have available two kinds of generating plants, one in which the prime mover is the turbine, and the other in which the prime mover is an internal combustion or Diesel engine. From a service performance standpoint, either plant is entirely satisfactory. However, from a fuel consumption standpoint, the Diesel plant has much in its favor. In most cases, the type of prime mover will be

dictated by the type of ship, that is, whether it be a steamship or a motorship. However, the Diesel driven generating plant must not of necessity be considered out of place on a steamship, as will be apparent later. Actually, the selection of the plant necessitates a complete economical analysis for the reason that our final interest is in the net monetary results.

Upon our ability to reduce our operating costs to actual rock bottom depends our future as a maritime nation. It is of paramount importance, however, that any improvements bear strict economic analysis when viewed with the ship problem as a whole. We must not accept a particular system, if the net result does not show an economic gain, even though it may, for instance, effect a very attractive saving in fuel. The problem of transporting and handling cargo at the least possible cost per unit, with the quickest turn-around, and with real service to the shipper, requires that the highest possible economy of operation be attained.

The auxiliary equipment on a ship is conveniently classified into two groups, namely, the deck machinery, including the winches, windlass, capstan and steering gear, and the engine room machinery, including the pumps, compressors, blowers, etc. The deck auxiliaries present some very interesting application and design problems, whereas the engine room auxiliaries present no problems of any real interest or concern. The economical advantages of the electrical deck auxiliaries are readily established. In the case of the engine room auxiliaries, however, a deeper analysis is necessary to show the improvements to be gained by the use of electrical equipment.

For this reason, the two classes will be discussed separately.

DECK AUXILIARIES

Considerable difficulty is encountered in securing reliable data on the power consumption of steam winches. Such data as have been obtained by actual test vary considerably.

Electrically Operated Anchor Windlass on the Motorship William Penn

Some of the variation can be accounted for by the difference in the hook loads, as it is obvious to those who have studied the field that the fuel required per ton of cargo handled varies considerably with the hook load, especially for loads under two tons. The remaining inconsistencies in the data are attributable to differences in condensation and leakage losses, differences in the initial and exhaust steam pressures, the relative condition of the engines, and the manner and method of handling the cargo, all of which are subject to wide variation.

ECONOMY

On the basis of carefully selected test data, supplemented by conservative calculations, it is not difficult to arrive at the relative fuel consumptions of the various types of winch

by the use of electric winches, due to the fuel saving alone, not to mention the saving in maintenance, the more expeditious handling of the cargo, and a number of very desirable but intangible advantages. It is only necessary to analyze the facts in any given case to show the advantages resulting from the use of electrical machinery.

MAINTENANCE

Maintenance is a very important consideration and has a proportionate bearing upon the final economical analysis. Here it has been established by practice that the maintenance costs of properly designed and applied electrical machinery have been practically negligible. This condition is as it should be, and as was predicted several years ago. It is true that there are indisputable instances where electrical appa-

Motorship William Penn. The Deck and Engine Room Auxiliaries of this Vessel are All Electrically Operated

systems. The following figures, therefore, are believed to represent the results of a conservative analysis. The relative proportions, however, are subject to difference of opinion, depending upon the data used in making the analyses. For instance, actual test data are available which show the fuel consumption of reciprocating steam winches to be more than 20 times that of electric winches supplied with power from Diesel driven generators, under practically identical conditions of cargo handling. Other cases show this ratio to be in the order of 12 or 14 to 1.

- (a) Electric winches supplied with power from Diesel engine driven generators (1)*
- (b) Electric winches supplied with power from geared turbine driven generators (condensing)..... (3 to 3½)
- (c) Reciprocating steam winches (15)**

*The fuel consumption for (a) is taken as unity for the sake of convenience.

**By assuming ideal conditions, and calculating the steam consumption for deck winches, results are obtainable showing a consumption of 3½ times that of the electric winches supplied with steam turbine generator power. It has been impossible, however, to locate actual test results anywhere near this figure, all being higher.

Analysis shows that in the case of the ordinary cargo ship, there is a saving equivalent to \$15,000 to \$25,000 to be had

ratus on board ship (particularly deck equipment) has necessitated considerable maintenance costs. However, proper examination of these cases shows that the apparatus involved is usually either of insufficient quality, improperly constructed, misapplied, or improperly attended. Deck equipment, in particular, requires a strictly high-grade class of electrical apparatus. There are several electrically equipped ships in service today which carry a very commendable record relative to their electrical auxiliaries, which incidentally are of high quality. It is to the electrical manufacturer's interest, as well as the shipbuilder's and ship operator's interest to insist upon strictly high standard and rugged apparatus. The better the quality, the more profitable is the investment.

Excessive maintenance costs are eliminated by careful selection of electrical equipment, and incidentally this is true of any kind of apparatus. We must not lose sight of the severe requirements imposed by deck winch service. Suitable apparatus can be supplied only after a thorough study and understanding of the problems involved. To obtain the proper results, it is necessary to design the motor, controller and resistor as a unit, and each part of the equipment must function with proper inter-relation, and the combined result

Forward Winches of M. S. William Penn

After Winches of M. S. William Penn

must be that which is required by the most expeditious, most economical and safest handling of the cargo.

Another important factor to be reckoned with in applying deck electrical apparatus is the deleterious effect of sea water. Unless extreme care is given to this consideration in the design and construction, and the apparatus made watertight to prevent the ingress of water when subjected to the wash of solid seas, nothing but trouble can be expected.

These are the reasons why only high-grade apparatus is suitable for the service. The maintenance of electrical equipment so designed and applied is considerably less than that of steam equipment including the steam lines.

OPERATION AND PERFORMANCE

In regard to the operation and performance, the salient features inherent in the electrical equipment are all that can be desired, and they may be summarized as follows:

The electrical equipment is capable of ample overload capacity. Its performance is uniform and independent of climatic conditions encountered. It is ready for operation at all times, and requires no preliminary warming up. Its efficiency remains constant throughout its life. It affords any desired degree of control of the loads and is positive in its

functioning. Its inherent characteristics are ideally suited to the load requirements in that it handles heavy loads at relatively low speed and light loads at relatively high speeds, and its extreme flexibility enables designs and arrangements to meet any desired condition.

INSTALLATION

The electrical equipment affords the greatest flexibility and convenience in installation for the reason that its location is not influenced by a desire to place the equipment in proximity to steam pipes or boilers. The cables for transmitting the electrical energy can be installed where most convenient, and their installation made permanent, whereas steam pipes must be installed with the idea of convenience and accessibility for inspection and maintenance. The maintenance of steam pipes is a very serious problem in many installations, while, on the other hand, the maintenance of properly installed cables of suitable quality is nil, barring, of course, mechanical injury.

RELIABILITY

It is doubted whether anyone would question the reliability of electrical apparatus for deck service. Electrical

Deck Winch Controller with Handle
Unshipped for SeaDeck Winch Controller Open for
InspectionDeck Winch Controller in Operating
Position

apparatus has not only proven 100 percent reliable in the hundreds of thousands of cases where it is applied on land, but also the large number of electrical installations on ship-board have proven its entire reliability. The simple rotation of electrical machinery with the consequent absence of wearing surfaces, except the bearings, is the principal reason for its record of reliability. The deck machinery constitutes the most severe application for electrical apparatus on board ship, and to insure its reliability it is merely necessary to build the equipment sufficiently rugged and watertight.

ENGINE ROOM AUXILIARIES

In the case of motorships, electrically driven engine room auxiliaries are the obvious and natural selection. In the case of steamships, however, there may be some room for argument in regard to the necessity for the improved economy afforded by the electrical system.

It is considered by many that steam auxiliaries are preferable for engine room service because their exhaust steam can be used for feed water heating. Nevertheless, the amount of steam consumed by the engine room auxiliaries, particularly at sea, is tremendous, and amounts to from approximately 20 to 30 percent of the total steam used at sea, depending upon the type and size of ship and propelling machinery. It has been argued that the substitution of electric for steam auxiliaries reduces the available auxiliary exhaust steam to a value below that required for feed water heating, and that for this reason the auxiliaries should be steam driven.

In view of the fact that the energy in the steam can be much more efficiently utilized by resorting to large expansion ratios, it is obvious that as much of the generated steam as is possible could be better used under more favorable conditions, that is, in auxiliary turbine electric units operating condensing while in port, and non-condensing, if necessary, at sea. Should there be insufficient exhaust steam for feedwater heating, it would not be uneconomical to bleed the main engines a sufficient amount to make up the balance required.

Analyses which have been made on this basis show that it is quite possible to make savings of fuel up to 10 and 15 percent in some cases of the total steam generated by the boilers of a ship with the usual steam engine room auxiliaries, not to mention other more intangible savings.

The amount of steam to be saved, or the net reduction in fuel consumption resulting from the electrification of engine room auxiliaries would depend entirely on the kind of ship and proportion of auxiliaries to main units. Economic analysis would have to be made for each particular case or each particular class of ships.

MAINTENANCE

By giving the proper care and inspection to the engine room machinery, its maintenance should be extremely small. One common cause for repairs in the case of engine room electrical machinery is the entrance of salt water into the machines, which results in grounded circuits and improper

commutation. However, by suitably protecting the motors, this cause can be eliminated. A drip-proof cover over the top of the apparatus will effectively prevent dropping water from entering the machine, and at the same time will not obscure the vital parts from inspection. In some cases where the motors are located in the bilge, it is desirable to resort to the enclosed, watertight arrangement. As a general rule, it will be found that apparatus which is easily and readily inspected will show the last maintenance.

OPERATION AND PERFORMANCE

None of the engine room auxiliaries presents any serious problem in motor application. The requirements for the most part call for continuous running, constant duty motors, having simple starters. The flexibility of the electrical system is so great that any desired performance or adjustments can be had readily.

INSTALLATION

Here again, the flexibility of the electrical system lends itself to the requirements of practically any installation arrangement, and the motors can be located wherever it is most convenient for the apparatus that they drive. The cables and controlling appliances can be installed wherever desired, and either manual or remote control can be supplied.

RELIABILITY

Here again, the past performance of electrical apparatus is sufficient testimony in behalf of its reliability, and it is a very simple matter to adequately take care of the light requirements of engine room apparatus.

INTANGIBLE ADVANTAGES

The following is a list of the most important intangible advantages of electric auxiliaries, as compared with steam:

(a) The electric auxiliaries are ready for operation on instant notice, and they eliminate the necessity for keeping steam on steam lines and valves of engines partially cracked so as to be able to operate the engine on short notice, and also to prevent these parts from freezing in cold weather.

(b) Any desired arrangement of control can be obtained with the electrical machinery, and, furthermore the control may be located wherever convenience dictates.

(c) The electrical machinery is considerably quieter in operation, and infinitely cleaner, as the reciprocating noises are eliminated, as also are the leaks from valves and pistons.

(d) In many respects, the electrical equipment is safer from the standpoint of injury to personnel because the voltages used are not sufficiently high to cause danger to life.

(e) From the standpoint of correct application to load requirements, the electrical equipment is far superior to the steam, in that the performance requirements can be very conveniently and accurately studied by the use of electrical instruments, thus placing the engineer in a position to know what he is doing, rather than to guess at his application.

(f) Electrical machinery adds to the living conditions on board ship, by virtue of the elimination of hot steam pipes, which often must be laid in locations where they are most objectionable.

An Economizer That Requires No Outlay

THE installation of economizing equipment in the boiler and engine room entails a first cost that must be balanced against subsequent fuel savings. If the first cost were eliminated, operators would never question the advisability of adopting such equipment. A real source of economy requiring no investment actually does exist in the engine room of every ship, but it is too often overlooked by the staff.

How this economizer can be utilized will be explained in the June issue of **MARINE ENGINEERING & SHIPPING AGE**

Steamship George Washington, Flagship of the United States Lines

Tuning Up the Engine and Boiler Room

Written on Board the George Washington as a Good
Example of What Can Be Done With Existing Ships

By William Bunker*

In order to keep a ship's propelling unit in an efficient operating condition it is first necessary to have well designed and well built boilers. Although many types have been designed and many more probably will be, the Scotch boiler leads today. There are many well known and competent engineers, however, who believe that a suitable multitube boiler when designed with sufficient steaming space is a better and more efficient unit than the Scotch boiler. This, however, is controversial.

The usual rule of thumb method for designing a Scotch boiler is to allow from 42 to 44 square feet of heating surface to one square foot of grate surface. This, in the opinion and experience of the writer, is erroneous. Some years ago the writer had charge of a vessel operating in the China trade, in which the boilers were originally fitted with 42 square feet of heating to one square foot of grate surface. This was changed by reducing the length of grate bars and constructing special bridge walls, thereby increasing the ratio to nearly 100 to one with the result of a 23 percent saving in fuel. This is a matter of record which a story may be published in a later issue.

Relative to bridge walls, I think it would be well to mention that the installation of modern ventilated bridge walls has been found to increase the boiler's efficiency. They also eliminate the labor of frequently rebuilding the brick bridge walls.

The present system of fitting tube retarders should be eliminated and the short grate bar fitted instead, getting the benefit of a high initial and a low terminal temperature which we now aim at but do not get with the retarders. Space at present does not permit me to go into the theory of combustion but it is hoped that this matter can be taken up at a future time.

SOOT BLOWERS A HELP

One of the modern practices which adds to the efficiency of the boiler plant is the installation of soot blowers, many types of which are excellent and a great many of which are useless. When soot blowers can be fitted to the back ends to blow with the draft they are of considerable advantage but where fitted as front end blowers they have a tendency to back up the products of combustion at the inside or further ends of the tubes and to reduce the efficiency of the boiler by plugging up the tube outlets. This is especially so when tubes are fitted with retarders.

In boilers fitted with the Howden forced draft system it is very often the practice to bank the fires too high when firing, using the upper air check over the furnaces. This is a bad practice. Fires should be carried light and even. Furnaces should be charged at short intervals and the doors closed as quickly as possible after the charging is performed.

Another evil that exists and seems to be inherited from ancient times is the promiscuous use of the slice bar. This tool in a well regulated and well organized fireroom is never used except in cleaning out fires. Of course, common sense

ought to teach even the least efficient firemen that they must keep their ash pans clear in order to prevent burning out grate bars and to allow enough air to consume the fuel.

INSULATION

All boilers should be thoroughly insulated. The best material for this is an 85 percent magnesia block fitted over a coating of chicken wire which leaves a dead air space. The whole should be covered with plastic cement and either lagged with a sheet iron covering or covered with a modern high class cement such as "Thorkote," which has given excellent results. All pipes should be thoroughly insulated

moving the bonnets, repacking the stems when found necessary, grinding valves in when same are found to seat poorly and putting same in good condition. A great deal of efficiency is lost by leaking valves in a steam plant, a fact that is especially true in marine work.

Fusible plugs are renewed at every yearly boiler inspection and steam gages calibrated at that time. While our steamboat inspection laws are sometimes considered too rigid there are two rules which are certainly correct, one is the installation of fusible plugs and the other is the drilling of staybolts. These screwed stays that are fitted between the combustion chamber and the shell of a boiler or between

Fireroom, Showing Method of Firing at Sea

with a magnesia covering. This comes molded in forms up to as large sections as will probably be used in any marine work. These sections should in turn be covered with canvas of double thickness, usually a No. 6, sewed in place. It should be added that all flanges should be covered with a special shaped covering made in halves, made removable in order to remake joints or set up on bolts when necessary.

Boiler water gages should be tested every day at sea and overhauled at intervals of at least once per month.

BOILER MOUNTINGS

Surface and bottom blows should be overhauled at stated periods not exceeding 60 days. This also holds good for water column valves, tri-cocks, gage glass fittings, main steam stops, auxiliary steam stops and last, but not least, whistle valve connections. These valves should be taken apart by re-

combustion chambers are drilled with 3/16 inch diameter holes to a distance of 1/2 inch within the sheet. This is done in order that the breaking of a stay may be discovered, water running out of the hole. One of the ex-German vessels operated by the United States Lines had the German staybolts in her boilers which were of a solid construction drilled to conform to the United States local inspectors' rule and the chief engineer on filling his boiler the first time found 15 staybolts were broken inside of the shell. This would not have been detected if the bolts had not been drilled. It is believed that in time this law will be enforced in European countries.

BOILER CLEANING

All boilers should be thoroughly cleaned inside and out at regular intervals. The external cleaning, as a matter of

routine, should be performed at every terminal port; internal cleaning should be performed at dates not exceeding 60 days. The modern ship is usually fitted with air compressor, and the use of pneumatic tools such as valveless scalers, etc., greatly assists the crew in performing this work. The use of compound is still a bone of contention but the engineer who uses clean water, kept slightly alkaline, is on the safe side. This can be determined either by the use of testing kits now supplied at reasonable prices or by reverting back to the old fashioned system of using litmus papers which will turn blue when the water is alkaline. This is a good practice and boilers are perfectly safe when the water is kept clean and slightly alkaline.

Care should be taken to see that all up-takes, breechings and connection doors, etc., are absolutely tight, as leaks here may lead to secondary combustion. This, however, should be followed up by the use of a gas analysis instrument.

RECIPROCATING ENGINES

Throttle valves on main engines should be kept steam tight, free and in good working condition. In reciprocating engines where a governor is fitted, this apparatus should be given periodical inspection and an overhauling at least every six months.

Considerable loss of steam is caused in many engines by the type of piston rings fitted to the high pressure cylinder. This cylinder, on account of taking steam from the boiler direct, is subject to greater heat and pressure than any of the others and special rings should be fitted to take care of this. For cylinders 24 inches in diameter and under a solid plug has been found very efficient. This should be fitted only when cylinder walls are true and they should be made large enough to travel over the counterbore so that when wear takes place another can be fitted and the cylinder walls kept parallel. Above this size, however, it is dangerous to fit the plug type close enough to be economical. The common snap ring does not give satisfaction at the temperatures and pressures now used for marine work of 200 pounds per square inch and over on account of the steam getting behind the ring and forcing

Sampling the Flue Gases with Orsat Apparatus

diameter of the cylinder. This gives a tolerance of 15/1,000 or approximately 1/64 inch in a 30-inch cylinder.

In cylinders of lower expansions snap rings usually work satisfactorily if made of the correct sections and proper material. It has been found, however, in the case of the low pressure cylinder on condensing engines that due to the pull of the vacuum it is necessary to fit a ring with considerable tension or to fit springs to keep the ring against the walls of the cylinders. Lockwood, Carlyle and rings of this type have proved very satisfactory in low pressure cylinders.

The care and up-keep of the valves in a reciprocating engine means much to the economy of the machine. High pressure valves are usually of the piston type and should be kept as nearly steam tight as possible. It has been found practical to have these renewed when a tolerance of over 6/1,000 takes place due to wear.

The intermediate valves should also be kept tight and the low pressure which is usually a slide valve should be examined at periods not to exceed three months and care should be taken to see that grooves or slots are cut in valve and seat to allow steam to penetrate for the lubrication of the surfaces. These slots or grooves should be kept clean and where relief rings or other means are fitted to the back of the valve to relieve the pressure they

Working Platform. Throttle Valve Is Shown Near Telegraph Dial That Communicates With Bridge. Feed Water Heaters in Background

should be kept tight and in a good working condition so that undue pressure will not occur on the valve seats.

The setting of valves is determined by the indicator cards and this should be followed up constantly so that the valves may be kept in a correct position to give a well balanced and efficient engine. Cut-offs should be adjusted to distribute the load equally throughout the different cylinders.

In many vessels, especially those in which forced draft fans are fitted in the engine room, it is found that considerable condensation takes place in the cylinders due to the cold air bath caused by air flowing from skylights. In these instances portable mats should be fitted over cylinder covers to retain the heat as much as possible and reduce radiation.

PACKING

Piston rod packing is another very important material that is used in marine engines of the reciprocating type. With saturated steam the ordinary type of packing with pressure

Low Pressure Cylinder, Showing Dome Fitted Over Tail Rod to Avoid Fitting Packing and to Eliminate Oiling. Vacuum Was Increased 1 Inch by This Change

breaker can be fitted if made of a suitable brand of white metal usually with a large percentage of lead on account of the temperature caused by the steam and friction. However, with superheated steam the packing is more of a problem and pressure breakers and wearing rings for the high pressure are made either of cast iron or composition metal, or a combination of both. In the fitting of cast iron the utmost care must be taken as to the composition and texture and the manner in which it is fitted. Unless unusual care is taken in this the result will be scored rods and a failure of the packing. Examination and overhauling should be done at periods not exceeding six months. Care must be used to see that wearing rings float, in other words, work freely against piston rods and that all joints are tight.

The old fashioned system of fitting packing to tail rods has been pretty well eliminated and the latest method is to fit domes over these rods thereby eliminating the use of packing. This method keeps the cylinder covers clean.

On large units, such as the main propelling engines, it is not considered good practice to fit packing with split joints, on packing boxes or gland. One reason is that it is almost impossible to fit a wearing ring to the rod and to the split gland at the same time. There is also the leakage of the joint in the way of the split.

OVERHAULING METALLIC PACKING

When dis-assembling packing, care should be taken to see that the wearing rings do not butt on the ends but are

allowed approximately $1/32$ of an inch clearance to take up for wear and to allow the metal of wearing rings to form a joint by close contact with rod and with the container on which they rest.

In the case of soft packing for auxiliary machinery, where it does not pay or is not feasible to fit metallic packing, care should be taken that a pure asbestos packing is not fitted to a running rod as the asbestos has a very bad effect on steel and will eventually wear grooves in the rod which means renewal in a short length of time. Some good wearing packings contain asbestos but always in conjunction with metal, that takes the wear against the surface of the rod.

BEARINGS

The fitting of bearings is a matter of routine work and should be laid out on a schedule where all bearings will be taken care of between every 60 and 90 days according to the need for same; this is usually determined by the amount of wearing surface allowed by the design of the engine. A great deal of undue wear is caused by neglecting the cutting of oil grooves and clearances, which is a very important matter and is usually not given attention. The crosshead brasses are usually the first to suffer through this negligence, and the average engineer forgets that his greatest difficulty is to get the oil on the top of the pin and keep it there, which is best done by cutting grooves to keep oil on top of the pin, allowing means for air to escape, and not by running the oil off the top and side of the pin. It is safe to say that the average engineer will reduce the best part of his wearing surfaces 20 percent by cutting improper oil grooves.

When the condition becomes acute and the bearings carry undue heat from this cause the shaft should be raised and either all bearings remetalled or at least those giving trouble should be filled and machined to size and thickness to conform to adjacent bearings.

A bridge gage is usually fitted to each engine and this should be used on main engines at intervals of about six months to determine the wear and alinement of the main crank shaft. The wearing down of the shafts usually does no particular damage other than to cause the shimming up of valves and connecting rods to keep pistons and valves in proper position, unless the wear takes place at certain points. This condition then becomes dangerous due to strain thrown on the crank shaft, bed plates, and reciprocating parts of the engine due to the lack of alinement. When the bridge gage shows undue or uneven wear on main bearings the coupling bolts on crank shaft should be removed and alinement checked by measurement of coupling flange. The proper adjustment of bearings is usually made by allowing a rule of thumb of $1/1,000$ of an inch tolerance to 1 inch diameter of shaft over ranges from 2 to 10 inches in diameter. Above this diameter it is usual to allow less clearance, which can be determined better by the action of the engine.

CARE OF BEARINGS

Care should be taken in the fitting of main bearings and also of crank pin and crosshead bearings to keep the brasses well up around the journal. A very bad practice that a great many engineers are guilty of is to ease off the sides with the idea of keeping the bearing running cool. This is a fallacy and is not practiced in up-to-date work.

Bearings need a slight clearance on the sides. This is usually arrived at by fitting the parting pieces so that the bear only on the ends and cut away in the center. This space acts as an oil-well and gives all necessary clearance for the carrying of oil, etc.

When arriving at the proper clearance or making adjustments on bearings lead wire is used between the shaft and bearing to ascertain the space between shaft and bearing. Care should be taken to use the proper sized lead, which should be slightly larger than the clearance required for

top of bearing. The leads are usually placed about 6 inches apart. When lead wire of too large a diameter is used and when placed closer together than mentioned above a false impression is taken so that when the leads are removed and the bearing put back it very often fits much closer to the shaft than the impression on the leads would indicate.

Where space is available feelers or thickness gages should be used which in the case of crosshead bearings very often

Main Thrust Bearing. Turning Engine Shown at Left and Sanitary Pump at Right

eliminates the necessity of stripping these bearings and using lead wire to get the clearance. The engineer must always watch the adjustment of his bearings, first to see that they are not too tight, which may cause heating and serious damage. He also should see that clearances do not become too great, for this is apt to cause a hammering effect by the journal shaft or pin, resulting in a loss of oil. The metal in the bearings is then apt to crystallize and if engine is allowed to continue for an undue length of time serious results are sure to follow, usually a broken shaft or pin.

THRUST

The thrust bearing fitted to this type of machinery is usually of the horseshoe type. These horseshoes are steel collars filled with white metal and should be kept clean and adjusted both as to tolerance and as to position as wear takes place by the thrust of propeller in driving the ship. Care must be used to keep the shafts set back to compensate for this wear in order to keep the crank shaft in alinement with the cylinders, piston rods, connecting rods, etc. The tolerance of these rings ranges from 4/1,000 to 15/1,000 of an inch according to the size and power of the engine.

The line shaft bearings which perform the function of holding up the shafting between the thrust and propeller shaft usually require little attention other than oiling excepting at intervals of two years when the tail shaft is removed for inspection to conform with rules set down by the classification societies and steamboat inspectors.

When a bearing of this description does cause trouble, usually by losing its white metal, through overheating or undue wear, it is usual to break the couplings on the shafts supported by this and adjacent bearings and then the metal is renewed and the shafts are lined up by comparison with the flange couplings fitted to each shaft.

Tail or propeller shafts are usually made of a high grade steel covered with bronze liners to keep out the sea water. These shafts run on lignum vitae bearings made by fitting wood of this kind on edge. They are bored to the same or a slightly larger diameter than the shaft, usually allowing 1/16

inch to the foot for clearance, which also allows the sea water to flow in and keep the shaft cool and lubricated while in motion. Many shafts are fitted with patent stern glands intended to hold lubricating oil in the stern tube but few are successful.

CONDENSERS

The condenser is usually a vessel constructed with a cast iron shell having a water box of the same material on each end and taking sea water at one end from a centrifugal pump. The water then passes through one-half of the tubes and returns from the opposite end of the condenser through the other half and is then forced overboard. A division plate is constructed to fit between the incoming and out-going water at one end and care should be taken that periodical inspection is made at every terminal port to see that this division plate is tight and in good condition. Many serious accidents to marine engines have been traced through the loss of this division plate at sea.

Fitted over each end between the water box and shell of the condenser there is a heavy brass sheet perforated to receive the condenser tubes. These tubes are usually $\frac{3}{4}$ inch in diameter (for commercial use) with length to suit the various condensers on the different ships. Holes in the tube sheets are first drilled to a diameter suitable to receive the tubes and then counterbored and threaded to receive packing to make a watertight joint around the tube and keep the sea water from mingling with the condensate.

In early days wooden ferrules were used for the purpose of making tight joints between tubes and sheet but of late years packing of different materials has been fitted around the tubes and compressed and made tight by the use of a ferrule screwed into the threaded gland, forcing the packing against the tube and against the shoulder in the tube sheet to form a water and air tight joint.

AIR PUMPS

After the water is condensed and falls to the bottom of the condenser it is then removed by an air pump and delivered

Air Pump in Foreground, Filter Boxes and Ballast Pump in Background

into the hot well. The air pump is a specially built apparatus which not only removes the water but also creates a vacuum by removing the air from the condenser. It assists the efficiency of the main engine by relieving the atmospheric pressure, which would otherwise operate against the low pressure piston.

(To be continued)

Oil Burning Affords Great Opportunity for Economy

Secret of Efficient Combustion Lies in Maintaining Proper Adjustment of Oil and Air for Twenty-four Hours of Each Day

By J. S. Milne*

THE keen competition that confronts the shipowner today has decreased the margin of profit and resulted in a demand for increased economies. Fuel is the most expensive item in ship operation and it affords a great opportunity for practical savings.

Many marine engineers think that all they have to do to burn oil efficiently is to turn on the oil and give it sufficient air to prevent heavy smoke. When asked to explain the high consumption, they invariably blame the equipment and are surprised to find that by applying a few of the principles of combustion to general practice, a substantial saving will be effected.

It is not the fault of the engineer for failing to obtain good results if his apparatus is not designed to give all the adjustments necessary for the proper control of air and oil, in order that complete combustion can be obtained with a minimum amount of air.

Complete combustion with a minimum amount of air is the secret of efficient oil burning. It cannot be obtained by judging the appearance of the flame in front of the furnace or the amount or color of the smoke from the stack, but by systematic use of instruments that are designed for determining the results to be obtained. Each fire should be adjusted individually, where it is possible, to give at least 12 percent CO_2 and all the others balanced with the same size tip on each burner and an equal distribution of air so that any variation in power can be obtained by increasing the oil pressure and the air without separate adjustment at each burner.

IMPORTANCE OF GOOD ATOMIZATION

The mechanical burner is the most generally used in marine practice. The oil is heated well above its flash-point and forced under pressure through the burner. The tip and atomizer give it a whirling motion causing the oil to break up into very fine particles entering the furnace in a hollow-shaped spray. The air for combustion is admitted around this hollow cone of oil. On an ordinary job it is seldom necessary or desirable to force air into the fire with sufficient velocity to pierce this cone-shaped spray of oil and still retain sufficient oxygen in the air to support combustion on the inside of this cone of oil. Assuming that it is only necessary to get the air that supports combustion in contact with the outside of the oil film, it will readily be seen how important it is to have good atomization with a real hollow cone and no oil issuing from the center into the furnace parallel to the walls, otherwise a higher air pressure is required with a lowering of efficiency.

The burners are usually designed with air registers, some of which give the air a circular or twisting motion and others a rolling motion. The real purpose is to get the proper amount of air in contact with the particles of oil as quickly and completely as possible, effecting combustion at the front of the furnace, care being taken to cut down the air supply to the minimum. When the job has been properly balanced and all the air adjustments made, it is necessary to maintain this condition continuously while operating. Steam requirements often vary, especially on passenger vessels, requiring the burning of more oil or the lowering of the pressure to suit different conditions of weather and requirements, thereby up-

setting all of the adjustments. Under these varying conditions, the use of accurate recording instruments helps the engineer to maintain an efficient system of operation and also keeps the chief engineer in touch with the performance of his juniors, having at all times a record of the condition under which the plant has been operating.

RECORDING INSTRUMENTS

There are a number of recording instruments for this class of work on the market, the most important of which are as follows:

- CO_2 recorder for stack analysis.
- Recording draft gage for air pressure.
- Recording stack pyrometer for temperature of escaping gases.
- Recording thermometer for temperature of fuel oil as supplied to the burners.
- Recording pressure gage for pressure of fuel oil supplied to burners.

The CO_2 machine is the most important and this should form part of every engineer's equipment as the use of this instrument is becoming more important each day. The recording instruments indicate immediately the changes occurring in operating conditions and permit the engineer to make the proper corrections at once. With this knowledge of conditions so readily obtainable, uncertainty and guesswork are eliminated, and the records obtained are a good check on the combustion performance and should be turned in with the log at the end of each voyage.

We have recently fitted a steamer with apparatus for regulating the amount of air required in accordance with the amount of oil burned on forced draft oil burning installations. The variation in oil pressure is controlled by a very ingenious arrangement for automatically regulating the air pressure, that is, if more steam is required, the governor on the oil pumps is set at a higher pressure. This automatically speeds the blower and keeps the supply of air regulated. This apparatus will effect quite an increase in operating efficiency as it does mechanically what we have been allowing unskilled firemen to do. However, it requires careful adjustment at the start and an interest on the part of the engineer force in its automatic operation.

Summarized, economy in oil burning necessitates the proper adjustment of the oil and air in order that the results can be as near to perfect combustion as possible and this condition should be maintained for 24 hours each day.

The economies resulting from the efficient burning of oil, while increasing the profit of the shipowner, must also be considered as an important factor in the conservation of our oil supply.

SHIPPING BOARD WAGE SCALE ADOPTED.—At a special meeting of the member companies of the American Steamship Owners' Association, held on April 23, it was voted that the official wage for unlicensed personnel in deck and engine departments of the American Steamship Owners' Association, effective at once, be the same as that now in effect on Shipping Board vessels, and that members be urged to subscribe to this wage and absolutely live up to it until same is changed by action of the Association in conference with accredited representatives of the Shipping Board.

*Chief Engineer, Todd Shipyards Corporation.

Meeting Competition by Using Superheated Steam

Operating Efficiencies and Costs of Superheated Vessels Compared with Those Using Dry Steam or Diesel Engine Drive

By Henry B. Oatley*

"I HAVE been shipmates with *saturated* steam for twenty years and see no reason why I should use superheated steam in our ships now." This statement was recently made to the writer by an official connected with a large steamship line operating under the American flag. Much can be read between the words quoted and much more can be said as to the effect upon our merchant marine of backward-looking attitudes of this nature, particularly in this day of high fuel and operating costs.

Competition will always be with us. If it is not offered by ships under other flags, it will be offered by ships under the American flag. When our competitors advance, we must advance further. If they save fuel, we must save more. If they decrease operating costs, we must lower ours an even greater amount.

In ship design and construction there are many factors which contribute to success or failure in the operation of that vessel. Many of the errors which may have crept in cannot be corrected except at prohibitive costs. This condition might be the result of errors in design of hull, which affect either speed, stability, or costs of handling cargo in or out of the ship. Many of these handicaps are capable of being removed at relatively small cost and can be made the means of turning losses into profit. Conditions of this kind are frequently to be found in the construction of boiler room or engine room equipment, methods for handling or burning fuel, and in the efficiency with which the energy in fuel is transformed into propulsive effect.

In this range of conditions the use of superheated steam stands out prominently. The contrast in thermal efficiency between saturated and superheated steam operation is well and favorably known. In all fields where steam-driven prime movers are utilized, superheated steam has become of widespread use, but it is remarkable that in marine service its general adoption has lagged somewhat behind railway and industrial power plant applications. During the last ten years, however, marine engineers have turned to superheated steam in increasing numbers as one very effective means of reducing fuel costs and thereby increasing net operating income.

Our American ships are, to a large extent, still operating inefficiently with saturated steam. It is true that during the war the Shipping Board Emergency Fleet Corporation gave some rather indefinite attention to the use of moderate degrees of superheat, but unfortunately the position of the board in this matter was hardly abreast of the development reached by other nations with large merchant fleets. The

large proportion of our ships which had been specified to use moderate degrees of superheat were, under the stress of war-time operation, operated with steam little more than dry.

NEED FOR IMPROVEMENT IN BOILER EFFICIENCY

Whatever may have been the reasons and the necessity for this, it is clear that we now must reconsider the situation and adopt all means that have been found effective in reducing the annual expense of ship operation, and which contribute to more revenue-paying ton-miles per year per dollar of operating cost. The time has now arrived when prejudice and old-time views must be brought out, placed on the table

and again analyzed in the light of present-day practice.

The arguments for and against the use of superheated steam have been so frequently discussed at much length in the engineering press that it is not considered necessary to again bring them into this article.

RESULTS TO BE GAINED FROM USING SUPERHEAT

The results, in economy of operation, perhaps have been given less prominence, and it is felt that reference to this "sine qua non" of the question should be gone into in some detail.

What has prompted large and well-managed steamship companies, such as the Cunard, White Star, Ellerman and others in England; the Compagnie Generale and

Mesagaires Maritime in France; the Nippon Yusen Kaisha in Japan and the Luckenbach, Ore Steamship Company and others in the United States, to install superheaters? It surely is not because owners desire to spend more money on their ships or to make any addition to already well-filled engine or boiler rooms. It is not because they are desirous of experimenting, nor is it because their passenger vessels can be advertised as providing additional comfort for passengers. It is because they have found from their own experience, which checked the results obtained by competing lines, that there were advantages represented by decreased fuel cost, increased revenue-paying cargo and, in many instances, because less space was occupied by the boilers to obtain the required capacity and because when coal is used as fuel there is a reduction in fire-room labor, with a consequent preference on the part of fire-room personnel for ships using superheated steam.

A list of all notable examples of vessels, wherein part or all of these advantages have been demonstrated, would read like a page from the Register of the American Bureau of Shipping. The *Homeric*, *Scythia*, *Carmania*, *Tyrrhenia*, *Empress of Asia*, and *Columbia*, among passenger ships; the *Bolton Castle*, *Kandahar*, *Adrar Baoule*, *Eclipse* (and other

Comparative operating records and trials indicate that increasing the superheat will increase the efficiency and give added fuel economy.

An increase of 50 degrees in superheat will give the same economy as an additional one-half inch in vacuum.

An increase of 50 degrees in superheat will give greater economy than an additional fifty pounds in boiler pressure.

Increasing the degree of superheat is far less expensive than providing for increased vacuum or increased boiler pressures.

*Vice-president, The Superheater Company, New York.

vessels of her class) the *Chilore* and *Marore*, and many other cargo vessels on the deep seas; also many hundreds of boats operating on lakes, rivers and canals could be named, all of which are using steam superheated above 500 degrees F. Most of the 3,000 vessels fitted with superheaters, not including our war-built merchant marine, use steam at 600 degrees or upwards.

Executives of steamship companies upon whom the responsibility for operating results may rest, are not so much interested in the number of ships equipped with superheaters as they are in the results obtained. They are interested only in whether or not they may be assured of:

1. Continuity of service.
2. Freedom from additional risk at sea.
3. Reduction in operating costs.
4. Cost of maintenance.

FEATURES OF SUPERHEATED SERVICE

Continuity of service is in no way jeopardized by the use of superheated steam, when apparatus of a proper design is fitted under proper supervision and operated with the same care and attention given to other equipment in the engine or fireroom. Like every other appliance aboard ship there have been instances of proper design installed under improper conditions, or of improperly designed apparatus, which have not given the full measure of satisfactory service. The widespread use of superheated steam in marine and other service should reassure the timid, or hesitant, executive, that suitable equipment is available and that the expected results can be obtained.

Freedom from additional risk at sea never has been seriously questioned, although it sometimes is referred to as "requiring proof." Many vessels on their maiden voyages have encircled the globe without a moment's delay, or a penny spent on repairs, and without a trace of any indication that the ship was at any time in danger. Important apparatus aboard a ship has to meet the requirements, and pass the inspection, of one or more official classification societies, or government inspection bureaus.

Reductions in operating costs are of greatest interest and most value when summarized. In Table I are given the total operating costs, showing the reduction by the use of superheated in place of saturated steam. A reciprocating engine vessel utilizing saturated steam has been used as a basis. This vessel was described in MARINE ENGINEERING AND SHIPPING AGE, March, 1923, page 138, with corrections of what appear to be typographical errors. With the use of 200 degrees of superheat a reduction in total operating expense, inclusive of a 10 percent return on the investment, of \$4,045 annually is shown.

TABLE I

	With Saturated Steam	With 200 Degrees F. Superheat
Total capital charge (29 percent)	\$70,800	\$73,660
Fuel used at sea and in port	95,000	85,240
Lubricating oil and make-up feed water ..	4,035	3,930*
Wages of crew	37,500	37,500
Subsistence	8,500	8,500
Tonnage dues and port charges	32,350	32,350
Brokerage and management	42,750	43,530
Stevedoring of cargo	119,700	121,880
Total operating expense	\$410,635	\$406,590

* 5 percent additional allowed for lubricating oil.

If the figure of \$412,000 in the reference referred to is correct, the saving would be \$5,410 annually. This reduction in operating cost would be obtained for a capital expenditure of not more than \$10,000 assuming that it was a superheater installation made in an existing vessel. The investment would be less, if the superheaters were installed when the vessel was built. Surely an annual return of upwards of 45 percent of the investment cannot be lightly disregarded.

In the comparison shown in Table I, no credit is taken for additional revenue-cargo permitted by a reduction in weight of make-up feed water and fuel required. This reduction amounts to 150 tons per voyage. An additional 150 tons of revenue-producing cargo per voyage yields (at \$4.50 per ton) an income of \$6,815 per year. This, added to the saving in operating cost, will more than repay the cost of superheater installation during the first year.

COMPARISON OF SUPERHEATED STEAM VESSELS AND MOTORSHIPS

The relative operating costs of, and investment in, motor driven and steam driven vessels has been widely discussed in the last few years. One of the most recently published,* and perhaps the most carefully worked out, comparison was contributed by Lawrence B. Chapman, professor of naval architecture, Lehigh University. The analyses were brought down to a basis of the "cargo rate to earn operating expenses and to pay a 10 percent return on the investment." It was shown that under the conditions assumed a Diesel engine driven ship, with steam auxiliaries and a geared turbine job with 100 degrees of superheat would, on a 5,000-mile voyage, be on a par with cargo rates at \$4.54 per ton. On a 10,000-mile voyage the Diesel drive would have an advantage over the geared turbine ship.

In the comparison referred to, 100 degrees of superheat was assumed for the turbine ship and only saturated steam for the reciprocating engine drive. Just why both steam driven vessels were placed on such a basis was not made clear. Believing that the hundreds of vessels operating satisfactorily for years with highly superheated steam justifies the assumption that the steam driven vessels in the comparison could be made much more attractive in operating costs, such calculations have been made. The two steamships in the article above mentioned have been figured through, using the same assumptions, general data and formulæ as used by Professor Chapman, but 200 degrees of superheat have been taken.

Using the same formulæ for steam consumption per shaft horsepower or indicated horsepower hour the 100 degrees increase in superheat for the geared turbine vessel results in a 7.4 percent steam saving; while the addition of 200 degrees of superheat on the triple expansion vessel gives a 15.2 percent steam economy.

Boiler efficiency, of course, is improved because of the increased amount of heat-absorbing surface, which causes a reduction in the waste-gas temperature of from 50 degrees to 100 degrees. The boiler efficiency in the turbine-driven vessel will become easily 72 percent instead of the 70 percent assumed by Professor Chapman. In the triple expansion engine job, where 200 degrees superheat is added, a boiler efficiency of 74 percent instead of 70 percent will be obtained from the Scotch boilers when fitted with firetube superheaters. These efficiencies, when used in the calculations for fuel economy, show 5 percent and 12 percent savings for the turbine vessel and reciprocating engine vessel respectively, and will check closely with the service results obtained from a large number of vessels.

In making the correction for the increased degree of superheat, arriving at the figures given in Table II, allowance has been made for the increase in weight due to the superheaters and for the cost of the superheater application and its installation.

THE HIGHER THE SUPERHEAT THE HIGHER THE ECONOMY

The efficiency ratio used by Chapman will be increased by the increased degree of superheat, because the benefits measured by reduced steam and fuel consumption per horsepower hour exceeds the calculated and theoretical figures based on temperature-entropy analysis. This increase, in

* MARINE ENGINEERING AND SHIPPING AGE, March, 1923.

the case of turbine engines, is partly the result of decreased windage losses and, in the case of reciprocating engines, partly the result of decreased valve and piston leakage. The efficiency ratio, therefore, for the turbine powered vessel has been changed from 0.62 to 0.63, and for the triple expansion engined vessel from 0.575 to 0.60.

By making the proper corrections in the items given in Tables I, II and III,* we find that the rate per ton of cargo necessary to give 10 percent return on the investment in addition to direct operating charges will, for the four ships, be as given in Table II.

TABLE II

Type of Propelling Machinery	Superheat, Degrees F.	Rate per Ton of Cargo to Give 10 Percent Return on Investment 5,000-Mile Voyage
Geared turbine	200	\$4.50
Diesel (steam auxiliaries)	...	4.54
Triple expansion	200	4.67
Diesel (electric auxiliaries)	...	4.82

The beneficial effects from an economy standpoint by running at low vacuum are well known, and are quite generally appreciated. The advantages of increasing the degree of superheat, however, assuming that low degrees of superheat have been used, are very well established, but are not so generally appreciated. On a number of recent investigations, the purpose of which was to determine the economies in fuel and in operating cost, these factors were analyzed in considerable detail. It was shown, for example, that the same additional economy in daily fuel consumption was obtained from an increase of superheat from 150 degrees to 200 degrees, as was obtained by increasing the vacuum from 27½ inches to 28 inches. Also that to raise the superheat from 100 degrees to 200 degrees resulted in a greater fuel economy than increasing the vacuum from 27½ inches to 28½ inches. The difficulty in constantly maintaining high vacuum is well known and many ships, particularly those operating in tropical waters, lose more than 1 inch of vacuum compared with their operation in the higher latitudes. In these comparisons a boiler pressure of 300 pounds existed. For lower pressures the same relation would exist between increased superheat and increased vacuum, although the percentage economy in both cases would have been higher.

The thermal advantages and consequent fuel economies with higher pressures also have been well recognized, but the gain from increased degree of superheat in comparison with the gains from the higher boiler pressures have been given less publicity. With a vacuum of 28.5 inches, 250 pounds boiler pressure and 150 degrees of superheat, the comparison shows that by raising the degree of superheat 50 degrees a fuel economy of 1.9 percent is obtained; while by increasing the boiler pressure from 250 to 300 a saving of 1.8 percent in fuel consumption is accomplished. It is admittedly less expensive in the first cost to increase the degree of superheat than it is to provide for higher boiler pressure, but it also is clear that both ways of effecting a reduction in operating cost should be given careful study.

The amount of superheat carried is independent of these conditions, and indicates one reason why continued and uniform economy from the use of the higher degrees of superheat is assured.

KEEPING SUPERHEATERS IN SERVICE

The cost of maintenance is difficult to state in definite terms, unless there be a very full description of the conditions existing. These conditions vary with the class of ship, character of service, ports touched, fuel used and last, but not least, personnel of the ship and policy followed by the steamship company as to maintenance and repairs.

Maintenance cost due to the use of superheated steam is as variable as repairs to other boiler and engine-room equipment. Information obtained from the owners of ships operating with high degrees of superheat shows that maintenance costs are not increased on the basis of total investment due to the use of highly superheated steam. A figure of 6 percent on the investment in the equipment will very fairly cover the annual repair, maintenance and overhauling due to the use of highly superheated steam. The maintenance cost included in Table I has been increased \$600 for the use of the superheaters. This is considered high when these costs taken from the records of many ships over a period of years are known.

In conclusion, it does not seem that the owners of American ships, faced as they are today with the necessity of scrutinizing operating conditions which include not only higher wages, but the very unstable condition of purchasing or building of vessels, can afford to disregard the advantages of all factors which are successfully utilized by their competitors operating ships under other flags.

The Diesel, in comparison with steam engine, is receiving very careful study, and the operating results of such ships will be a matter of vital importance. There is, however, ample evidence to support the contention that the steam-driven vessel—admittedly capable of very great improvement—is superior under many operating conditions to a ship propelled by internal combustion engines, and in this contention the further improvement of the Diesel or semi-Diesel engine is not disregarded. The geared turbine or the turbo-electric-driven ship with high degrees of superheat, and with higher boiler pressures, has proven, in the recent past, and without much doubt will continue to demonstrate, its advantages for the powering of our ships.

Plaintiff's Rights in Limitation Suits

WHERE the plaintiff in a limitation suit has settled claims abroad, arising out of a collision in respect of which the decree of limitation has been obtained, he is entitled to bring payment of such claim into consideration before the registrar when the administration of the limitation fund is decided upon. Proof of such payment may be brought before the registrar notwithstanding that such payment was made under a foreign system of limitation, or for an amount not limited according to the English rule of limitation. It is not material that the claimants to whom such payment was made were not subject to the jurisdiction of the Court.

The steamer *Dokka* and her cargo were sunk in collision with the steamer *Coaster*. After the collision the *Coaster* put into a French port, where her owners were forced to give bail in order to secure her immunity from arrest at the suit of the owners of the *Dokka*. Bail was given in an amount equal to the value of the *Coaster* at that time, which was the full amount of the liability of her owners under the law of France. In subsequent proceedings in France the *Coaster* was held alone to blame, and her owners were condemned in the amount of their bail and costs. The owners of the *Coaster* discharged the judgment debt and then commenced proceedings to limit their liability in England. A decree of limitation was pronounced and at the subsequent reference a claim was filed by the owners of the cargo laden on the *Dokka* and the owners of the *Coaster* themselves also filed a claim for the amount they had paid under the judgment in France, together with their costs in the French proceedings. The registrar allowed their claim for the amount paid to the owners of the *Dokka*, i. e., the amount of the statutory liability of the owners of the *Coaster* in France. The English Supreme Court of Indicture in Admiralty held that the claim was properly allowed. *Aspinall's Maritime Law Cases*. Vol. XV, Part VII, page 560.

How to Buy Fuel of Proper Quality at Lowest Price

By Major George M. Talbot*

IN the present era of low freight rates and high operating expenses the fuel bill, which usually represents from thirty to forty percent of the actual operating expenses in steamship operation, should be given first consideration in order to reduce its cost to the absolute minimum consistent with efficient operation of the vessel under consideration.

The most important problem is to procure fuel of a proper quality at all times at the lowest possible price.

In purchasing coal and oil, the purchaser should carefully study conditions affecting the market value of these commodities and endeavor to contract for requirements when the market value is lowest. While some purchasers of coal and oil prefer to take their chances on the open market or make

Study the market conditions carefully and buy right.

Buy on a long term contract and avoid the market fluctuations.

Be sure the quantity and quality of fuel you buy are actually delivered.

Keep your "burning equipment" in efficient condition.

Employ only competent and efficient engineers and firemen.

short term contracts, the writer prefers the long term contract covering one year or longer. By making a long term contract with a reliable supplier, who can guarantee performance, the purchaser will usually avoid the market fluctuations. He is thus enabled to undertake long time freighting contracts and know in advance what the largest single item of his operating cost will be.

FUEL OIL

The question of quality is an important one. In purchasing fuel oil the purchaser should consider using the lowest grade of fuel oil that his burners can handle efficiently, bearing in mind that if he demands too high a grade of fuel oil the refiner is compelled to leave some of the more valuable by-products of crude petroleum in the fuel oil, and, therefore, must obtain a higher price for this commodity.

A grade of fuel oil that the majority of vessels can handle

*Assistant manager, fuel department, United States Shipping Board Emergency Fleet Corporation, Washington, D. C., and member of Fuel Conservation Committee.

S. S. Aquitania Taking On 55,000 Barrels of Fuel Oil in 9½ Hours

efficiently, if the vessels' bunker tanks are equipped with facilities for heating the oil, is commercially known as bunker oil "C." This grade of fuel oil is considered the most economical fuel on the market today.

In producing this grade of oil the refiner is able to extract from the crude petroleum the lighter and more valuable fractions, leaving a residuum oil that is entirely satisfactory for use as fuel. The calorific value of the residuum usually runs about 2.5 percent less than the crude from which it is extracted.

POINTS TO SPECIFY

As a guide to the purchaser in preparing his specifications the following are the most essential points to cover in order to be assured of a proper quality of oil:

Flash Point. In order to comply with insurance regulations and minimize the fire hazards, it should not be lower than 150 degrees Fahrenheit, test to be made in a closed tester.

Water and Bottom Sediment. Water and bottom sediment in the oil should not exceed two percent.

Viscosity. The viscosity should not exceed 300 seconds at 122 degrees Fahrenheit, test to be made in the Saybolt Furol, Viscosimeter or equivalent results if test is made on other instruments.

It is not necessary to specify the number of British thermal units to the pound of fuel oil, for the reason that the fuel oils supplied by the principal oil companies throughout the world seldom vary more than five percent in British thermal unit value. This, however, is not the case with bunker coal whose British thermal unit value varies in different localities as much as twenty percent.

VISCOSITY SPECIFICATION MORE ACCURATE

Although it has been the custom in the past to specify an oil of a certain specific or Beaume gravity in order to determine one of the principal characteristics of the oil, i.e., its fluidity, a gravity specification does not determine this feature with sufficient accuracy, and, therefore a viscosity specification has been substituted which more accurately represents the nature of the oil.

A great many are of the belief that viscosity and gravity are closely related. This is not the case as evidenced by the following definitions of these terms:

Viscosity is a measure to determine the fluidity of a liquid, its internal friction or its resistance to flow.

Specific gravity as applied to liquids is the method used to determine the weight of a liquid and is defined as the ratio of the weight of a given volume of a liquid to the weight of an equal volume of fresh water.

Beaume gravity is another method consisting of the use of a hydrometer to determine the weight of a liquid.

As a further indication that these two terms are not closely related, it has been found that it is possible for a 16-degree Beaume fuel oil extracted from a naphthene base crude oil to have a greater viscosity and, therefore, to be more difficult for pumps to handle at a temperature of 100 degrees Fahrenheit than a fuel oil of 13-degree Beaume at the same tem-

perature, which was extracted from a paraffin, or mixed base crude oil.

Notwithstanding these facts which should be apparent to any student of the subject, some purchasers of oil still insist on a higher gravity specification when what they really seek is a lower viscosity.

BUNKER COAL

In purchasing bunker coal, some follow the custom of purchasing under a trade name or under a recognized classification, others purchase under an analysis specification, while still others make the mistake of purchasing almost any kind of coal that can be procured at the lowest price. There is no doubt but what it is more economical to purchase the highest grade of coal that can be procured, provided there is not too great a price differential.

The writer will not attempt to establish anything that might be considered as a proper price differential in the different grades of coal, but I think that it is reasonable to assume that, if one coal is five percent higher in ash and fifteen percent lower in British thermal units than another coal with approximately the same percentage of volatile, fixed carbon and sulphur, it is twenty percent less efficient and, therefore,

worthy twenty percent less.

Wherever it is possible to procure what is commercially known as a high grade semi-bituminous coal and practicable to purchase under an analysis specification, I consider this method most desirable.

ANALYSIS OF GOOD BUNKER COAL

Coals of the following approximate analysis should be considered good coals for marine use:

Volatile not over 24 percent.

Fixed carbon not less than 66.5 percent.

Ash not over 8 percent.

Sulphur not over 1.5 percent.

British thermal units, dry coal, not less than 14,500.

In some localities coals can be procured that will produce a better analysis than the above, while in other localities the best coal obtainable will not equal the above analysis.

CONCLUSIONS

In summarizing the above, the following are the most important features that should be given the closest possible supervision in order to reduce the fuel cost to the absolute minimum:

1. Study the market conditions carefully and buy right.
2. Be absolutely assured that the quantity and quality of fuel that you purchase is actually delivered to your vessel.
3. Keep vessels' "burning equipment" in proper repair to efficiently burn the fuel.
4. Obtain from vessels' personnel the highest possible efficiency in handling and burning fuel aboard the vessels.

BULLETIN No. 126, entitled "An Investigation of the Fatigue of Metals, Series of 1922," is the second report to be issued on the investigation of this subject by the University of Illinois. Copies may be obtained without charge by addressing the Engineering Experiment Station, Urbana, Illinois.

Does it Pay to Have a Satisfied Crew?

CAPTAIN JOHN F. MILLIKEN, secretary of the Neptune Association, states in a feature article which will appear in the June issue of MARINE ENGINEERING AND SHIPPING AGE, that "sooner or later our shipping men will discover that the cheapest men are not always the most economical and that a satisfied crew pays real dividends."

One suggestion he offers to attract men to the service and to make the operating problems their own is to encourage them to purchase a few shares of stock. As stockholders in a company these men will take a personal interest in the success of the fleet.

Designing the Marine Power Plant for Efficiency

Analysis of Factors Affecting the Economy of Various Types of Main Drive, Auxiliary Equipment and Economizers, with Practical Examples

By Warren B. Flanders*

THAT greater efficiency in the operation of steamships under the American flag is not only needed, but will be obtained, is evidenced from the great increase in attention being paid to this subject. This is evidenced not only by the operating management, who take a keen interest in the subject from the dollars and cents point of view, but by the engineering personnel as a matter of professional interest.

Of recent years there has been great progress in the development of the steam turbine and its use for ship propelling machinery. This development has progressed along the lines of the direct-connected turbine (for use with the higher speed vessels only), the single reduction geared turbine, the double reduction geared turbine and the use of generators and motors between the turbine and propeller. (These three systems are applicable to moderate or low powers as well as high.) In this development there has been a marked advance in economy, and numerous reports have established the relative efficiencies of these types of equipment. The following table, therefore, might be taken as a fair statement of the relative performances in the way of steam consumption of the different types for the same class of vessel, where superheat is not employed.

TABLE 1

Type of Propulsion	Steam Consumption per Shaft Horse-power Hour—Main Engines	Relative Consumption Percent
Triple expansion	15.0	128
Direct connected turbines*	13.0	111
Single reduction geared turbine	12.7	109
Electric drive	12.2	104
Double reduction geared turbines	11.7	100

*Used for large powers only.

On the basis of the same conditions of steam pressure and quality of steam, this comparison indicates the progress that has been made in better economy in the engine room and, of course, reduction in steam consumption means a similar reduction in fuel consumption with a net saving to the operators of the percentage indicated.

SAVINGS POSSIBLE WITH SUPERHEATERS

Further savings have been effected by the use of superheaters, and undoubtedly great progress is being made in this direction, the high speed gear or electric drive turbines making possible the utilization of high superheats with safety. Thus, with 100 degrees superheat, the steam consumption of the engine room may be reduced 10 percent and, as the same, or even slightly higher boiler efficiency may be obtained with this amount of superheat, the fuel consumption will be decreased 5 to 6 percent. With higher superheats, further gains may be expected, and there is a tendency to use even as high as 200 to 250 degrees superheat in certain cases. This, however, means a total steam temperature of from 600 to 700 degrees F., and entails special attention in the way of design of piping, valves and

miscellaneous equipment, especially pumps and other auxiliaries.

It is usual to indicate savings due to superheat as based on the use of dry and saturated steam and as savings in steam consumption. The matter of real interest is the net savings to be expected in *fuel* over the use of steam as normally delivered by the boilers. Fig. 1 has been prepared therefore, showing this saving based on the use of steam with a quality of 98 percent. The saving in steam consumption has been corrected for the additional heat required to superheat the steam and a constant boiler efficiency is assumed.

Some authorities claim 50 degrees of superheat may be obtained by waste heat superheaters with no increase of fuel

Fig. 1.—Saving in Fuel Consumption by Use of Superheat Based on Steam at 200 Pounds Gage Pressure, 98 Percent Quality, and Vacuum 28½ Inches in the Exhaust

consumption, in which case the curve would be as indicated by the dotted line.

HIGHER BOILER PRESSURES ECONOMICAL

Increased attention is being paid to the use of higher steam pressures combined with higher steam temperatures in the form of superheat, and it is not improbable that in a very few years a steam plant operating with 600 pounds pressure and 200 degrees superheat will be not uncommon. There are many problems, of course, to be worked out in connection with this progress, and these center largely around the selection of the auxiliary equipment on the ship and the methods of feedwater heating. The question of design of boilers, piping and main turbines may be said to be practically solved and it only awaits someone with sufficient initiative to go ahead with the carrying out of an actual installation.

By the use of 500 or 600 pounds steam pressure at a temperature of 600 to 700 degrees F., together with a suitable arrangement of auxiliaries, with particular attention paid to the heating of the feedwater, involving possibly the use

*Engineer, Marine Department, Westinghouse Electric & Manufacturing Company, South Philadelphia Works.

of economizers and air heaters, a fuel consumption for a 3,000 shaft horsepower vessel of 0.6 pound of oil per shaft horsepower is not an impossibility.

It is obviously necessary in order to attain such a performance that everything entering into the equipment be of the highest quality; that the ship be maintained in the best possible condition and the operating personnel be of the highest order of intelligence and ability, combined with a willingness to keep everlastingly at the details of operation. These are just the elements which may be expected in the American merchant marine, so there would seem to be no great obstacle in the way of this attainment.

FURTHER ECONOMIES IN THE BOILER ROOM POSSIBLE

There still seems to be a great deal of room for improvement in the economical operation of the average ship, and the greatest field in this direction is undoubtedly in the boiler room. C. J. Jefferson, in a paper recently read before the American Society of Mechanical Engineers, pointed out the possibility in this direction. Boiler plants, which average in service from 60 to 65 percent efficiency, as determined by actual investigation of many ships, are shown to be capable of operating with 80 percent efficiency or better, by merely paying proper attention to the firing conditions and in the maintenance of the boiler equipment in satisfactory condition. This item alone shows a possibility of saving 20 percent of the fuel used on the average vessel. Recent trials with a 1,500-horsepower equipment having oil-fired watertube boilers, made under actual sea conditions, show a similar saving possibility. An average consumption of oil a day of 20 tons for a large number of sister ships was reduced to 16 tons for a single ship when operated under a careful supervision, directed especially towards the economical burning of the oil.

WASTE ELIMINATION IN AUXILIARY UNITS

Next to the boiler room, the most fruitful field for improvement in economical performance is in connection with the feedwater heating system and the selection and operation of the auxiliaries. In an older type of engine drive, many of the principal auxiliaries were driven directly from the main engine, and this, combined with a moderate degree of feedwater heating, led to a degree of economy which offset some of the advantages to be obtained from the geared turbine installation. With the rapid development of this latter form of drive, the auxiliaries were largely separated from the main engines and little attention was paid, in many cases, to their economical operation. Comparatively wasteful direct connected turbines, or even reciprocating engines were used for driving circulating pumps, etc., with the result that the overall economy was in many cases disappointing.

The auxiliaries are necessary to the operation of the main machinery and the ship and may be classed as "Engine Room" and "Miscellaneous."

The engine room auxiliaries may be taken as:

- Boiler feed pumps.
- Boiler fuel oil pumps.
- Boiler blowers or fans.
- Condenser circulating pumps.
- Condenser air removal apparatus.
- Condenser condensate pumps.
- Turbine lubricating oil pumps.

The miscellaneous auxiliaries may be listed as:

- Ship lighting and power sets.
- Ballast pump.
- Fire and bilge pumps.
- Sanitary pumps.
- Refrigerating machinery, etc.

The total number of steam driven pumps and blowers of a large passenger vessel recently described, reaching the number of fifty, varying all the way from a 4½-inch by

2¾-inch by 4-inch horizontal hot water circulating pump, to the two 10,000 gallons per minute main circulating pumps.

THE HEAT BALANCE SHEET

A study of this equipment naturally brings up the subject of heat balance and plant economy.* Heat balance in engineering language at one time meant but one thing. It was a balance sheet, just like a financial balance sheet, in which the British thermal units in the fuel are balanced against the total British thermal units expended. Such a balance sheet is shown in Mr. Jefferson's paper above referred to, of which the following is an example:

Heat absorbed by boiler and superheater, percent....	84.6
Loss due to burning hydrogen in fuel, percent.....	6.0
Loss due to heat carried away due to dry gas, percent.	3.8
Loss due to carbon monoxide, percent.....	.2
Loss in unconsumed oil and unaccounted for, percent..	5.4
Heat in fuel as fired, percent.....	100.0

This shows the heat balance for the boiler room, and as far as this particular department is concerned, 84.6 percent of the heat in the fuel is delivered to the steam ready for use in the engine room.

Another heat balance of the same kind may then be made up for the engine room and this will show:

Heat turned into useful work on the propeller shaft, percent.....	15.4
Heat used in auxiliary power, percent.....	1.5
Radiation and leakage, percent.....	2.8
Heat rejected to sea water in condenser, percent....	64.7

Total heat received from boiler room, percent.....84.4

The above balance sheets are for an economical plant in which power would be produced for 0.91 pound of oil per shaft horsepower.

The term "heat balance" is now taken to also cover the preservation of a proper balance between the feedwater heating requirements and the amount of steam available from the auxiliary machinery for efficient feed heating.

When the large percentage of heat rejected to the sea water is considered, it is obvious that every attempt must be made to keep this amount low, and wherever possible, steam should be so used that any heat remaining therein after doing work, may go back to the boiler through the means of the feedwater, rather than be discharged to the condenser, where it is irrevocably lost. This form of heat balance deals directly with the choice of auxiliaries and their drives, such that the steam used by them, either directly or indirectly, will balance the feed and other heating requirements in so far as this can be done. The reliability of the auxiliaries is of primary importance and has a deciding influence on the choice.

ARRANGEMENT OF AUXILIARIES

There are many arrangements of auxiliaries and methods of drive, all with their different relative reliability and it is the economic phase of this matter that of late years has received very considerable attention on the part of stationary engineers, with the resultant considerable improvement in power plant economies.

The steam having passed through the main turbine and having been condensed, is usually delivered to the feed and filter tank, where it mixes with various drains and in some cases is given some heat from air ejectors or the exhaust from small pumps, etc. From there, it is usual to pass the feed through some form of feedwater heater, into the boiler. A feedwater heater may receive steam direct from the boiler and thus heat the feedwater to the temperature of the boiler steam, or the feed may be pumped into the boiler by

*Much of the material which follows was suggested to the author by Mr. Francis Hodgkinson, chief engineer, South Philadelphia Works, Westinghouse Electric & Manufacturing Company.

means of an ejector, the steam used in which heats the water directly with no loss of heat units. With the feed and the boiler alone considered, this operation is carried out at 100 percent efficiency, except for radiation. Such installations of heating by boiler steam have been actually made for the purpose of avoiding varying temperatures and consequent strains in the boiler. A case of this kind is reported in the harbor tug *Dresden* in Boston.

ENGINE EXHAUST USED FOR HEATING FEEDWATER

Considering the power plant as a whole, however, steam to be used for heating feed should be allowed to do as much useful work as possible, by expanding in an engine (turbine or reciprocating), when, with ordinary efficiencies, power may be produced for some purpose with but a use of 6 to 7 percent of the water heating capacity of the steam. Thus, considering boiler steam as a medium for heating, useful work may first be done and the exhaust used for the heating process, with a very slight loss in the heating capacity. Thus, it is possible, with steam at a pressure of 200 pounds at 98 percent quality, exhausting at 8 pounds back pressure, to produce a horsepower in the auxiliary turbine with 34.5 pounds of steam and assuming that the exhaust steam will give up all its heat at the exhaust pressure, we have the following balance:

Total heat in steam at 200 pounds... 1181.9 British thermal units
Total heat in liquid at 8 pounds.... 204.1 British thermal units
Heat available for work or heating.. 977.8 British thermal units
Heat used in doing work $2,545 \div 34.4 = 74.0$ British thermal units
($2,545 =$ British thermal units per horsepower)
Heat available for heating..... 903.8 British thermal units
Efficiency of work process $903.8 \div 977.8 = 0.925$

ECONOMICAL LAND INSTALLATIONS

The majority of economical land power plants are used for generating electricity and the main operating machinery runs at practically constant speed, and the electrical energy is generated at constant voltage. It has, therefore, been the rule in such plants to drive some of the auxiliaries directly by steam and some by electric motors. This permitted numerous arrangements for feedwater heating by means of steam which had done some work. Among these methods may be cited the following:

- A. Steam drive is used for such auxiliaries so that the exhaust steam condensed in a feedwater heater will give the feedwater temperature corresponding to the exhaust temperature of the auxiliaries, at the average operating condition of the main power unit, the balance of the auxiliaries being motor drive.
- B. The same general arrangement as "A" is followed, except that the auxiliary units are selected so as to give the maximum feedwater temperature at the full load of the main unit, and automatic means are provided for admitting the excess auxiliary exhaust steam into a suitable stage of the main power unit when this unit is operating at the lighter loads, when there will obviously be more auxiliary exhaust than can be used for heating the feed.
- C. The same arrangement as "A" is employed but with the addition of an automatic valve, which at light load on the main unit, permits the excess auxiliary exhaust steam to be admitted to the main unit, as in the case "B," and of a second valve, which at times of heavier than average loads, admits steam from a higher pressure stage in the main unit to make up the deficiency in exhaust from the auxiliary unit.
- D. All auxiliaries are driven direct from the main unit, usually through the use of electric motors taking power from the main turbine driven generator. The feed heating is accomplished by bleeding the turbine of the steam which can be condensed in the feedwater heater.
- E. A power unit is installed in addition to the main unit, this power or auxiliary unit operating a generator independently of the main turbines, and all of the auxiliaries are operated by means of motors from this auxiliary generating unit. The exhaust of this auxiliary unit is condensed in the feedwater heater giving the desired temperature.

- F. The same arrangement as in "D" is used, except that certain of the auxiliaries, in addition to the motor, have a steam turbine drive, the motor receiving energy from the main generating unit or from the steam turbine, which later may be controlled from time to time so as to give just the amount of exhaust steam necessary to maintain the feedwater temperature.

In the above feed heating systems, except possibly "D," the temperature to which the feedwater may be raised is that of the temperature of the auxiliary exhaust steam. It would certainly be economical and beneficial, from the mechanical standpoint of a boiler, if the feedwater were heated somewhere near the temperature of evaporation. To do this, the water could be heated by steam direct from the boiler, but this would give a mechanical advantage only. The system "D," outlined above, could be arranged to bleed the steam from the main turbine at several points, each at a different pressure and each using its separate feedwater heater. This would certainly be economical, but would quickly become impracticable, because of the cumbersomeness of the heaters if many stages were employed.*

USE OF ECONOMIZERS

Another method of accomplishing this additional feed heating is by means of economizers, where the waste gases from the boilers pass through heating elements to which water is admitted at the temperature of the feed heater and brought up to as near boiler temperature as practical. Economizers have been used in marine practice. (Admiral Dyson shows an arrangement in his book on page 82 in the case of Belleville boilers.)

So far as land practice is concerned, economizers are accepted as a standard equipment, and they certainly are a vital factor in obtaining high plant efficiency. Where higher steam pressures are to be employed, it would seem that the economizers become practically necessary, if the full benefits of the high pressure are to be realized. At ordinary pressures, whether or not the cost of the installation is warranted, depends upon the cost of fuel and the maintenance charges of the economizers. It is probable that their installation can be shown to be warranted in almost any case from an economic standpoint.

Reference has been made to the condensing of the exhaust steam in the feedwater heater and it should be borne in mind that the condenser and the feedwater heater are exactly similar pieces of apparatus performing the same function, i. e., the use of water to condense steam. In one, the condensing of the steam is the primary object, and the heat is lost. In the other, the conservation of the heat is the primary object, and the condensing of the steam becomes secondary.

TYPES OF FEEDWATER HEATERS

As in condenser practice, there are surface and jet condensers, so with the use of feedwater heaters, there are surface and jet types. The jet types are usually referred to as open feedwater heaters, this name coming from an ancient land practice where the heater was actually opened to atmosphere. In marine work in this country the practice has been to use only the closed or surface type of feed heater, and this is probably one of the contributing causes of the severe corrosion often found in boilers and turbines aboard ship. With this form of heater it is usual for the water to enter at a pressure in excess of that of the boiler and, therefore, even though it may be heated to a temperature of 235 degrees F., it is very far from the actual boiling point. With a feedwater pressure of 300 pounds and a temperature of 235 degrees F., the water is 187 degrees below the temperature of evaporation. The result of this is that the air which is almost certain to be included in the feed-

*A discussion of this is given in Dinger's "Naval Machinery," pages 160 to 163.

water, does **not** separate or boil off from the water. Were the water in this same heater kept at the pressure corresponding to the temperature, a very large percentage of the air would be driven out and, if the jet form of heater were used, where the water and steam actually mixed, a very large percentage of the air would be expelled without difficulty. By proper venting of the heater, this air can be permanently removed from the feed.

This jet form of heater might well be incorporated with the feed and filter tank, or if it were still desired to have them separate, the feed and filter tank could be raised and the water allowed to flow to the jet heater and the feed pumps would draw their water from it and deliver it to the boilers. It is obvious that the heater must be located at some elevation above the feed pump so that the water actually in the pump will be below the temperature of evaporation, although the water in the heater may be actually boiling.

With this type of heater vented through a small tubular heater, so that any steam escaping with the air is condensed by the feed passing through the tubular heater, it is possible to obtain a feed temperature corresponding to the temperature of evaporation of the pressure in the heater and this is done without wasting any heat or permitting any steam to escape to atmosphere.

OXYGEN IN THE FEEDWATER

It is very easy for oxygen to enter the feed system and it is very important that as much of it as possible be removed. A common cause of air in the feed is leaks in the glands or stuffing boxes of the feed pumps. Another common cause is for the feedwater to fall through the open air

Fig. 2

into the feed and filter tank; this may be very serious. Slight air leaks in the vacuum system are responsible for considerable oxygen in the feed. It is, therefore, desirable to keep the system as tight as possible and to take every precaution to prevent air getting into the feed, and, in addition, to do whatever can be done to drive the air out of the feed after its unpreventable inclusion.

Taking up again the types of auxiliaries and their relation to the feed heating system in merchant marine work, none of the arrangements "A" to "F," inclusive, listed above, is ordinarily employed. This is because the load condition is essentially a constant one. Practically all of the auxiliaries are steam driven, each with its independent steam cylinder, engine or turbine, and it is almost certain that the steam which will be exhausted from these various units, which are necessary to the operation of the ship, will be in excess of that required for feedwater heating.

PRACTICAL HEAT BALANCE EXAMPLES

Bearing in mind that the passing of heat to the condenser **must** be avoided, any improvement in the efficiency

of the steam consumption of the auxiliary units is desirable. This is perhaps best illustrated by examples of heat balance under conditions approximating those actually obtained in practice. These examples are based on a cargo-carrying ship equipped with geared turbine driven propelling machinery and operating the greater part of the time at the normal load of 3,000 shaft horsepower. The steam pressure is assumed to be 200 pounds gage at a quality of 98 percent and the vacuum in the exhaust is assumed to be 28½ inches mercury referred to a 30-inch barometer.

Table 2 gives the assumed power and steam consumption of the various auxiliaries as they would be operated under the average steaming condition.

TABLE 2

Auxiliary	Type	Horse-power	Pounds Steam per Hour
Boiler feed pump	Reciprocating	15	1,500
Boiler fuel oil pump	Reciprocating	2	200
Boiler blowers	Centrifugal, engine driven	12	500
Condenser circulating pump....	Centrifugal, geared turbine drive	60	2,300
Condenser air removal apparatus	Ejectors		900
Condenser condensate pump ...	Centrifugal, turbine drive	4	400
Turbine lubricating oil pump ...	Reciprocating	2	200
Lighting set—15 kilowatts	Turbine Drive	23	1,100
Miscellaneous auxiliaries	Reciprocating and turbine drive	30	2,500
Total		152	9,600

Example 1—Steam Driven Auxiliaries—No Feed Heating

Steam pressure—200 pounds gage.
Steam—98 percent quality.
Vacuum in exhaust—28½ inches.
Shaft horsepower—3,000.
Steam consumption—main turbines—11.7 pounds per shaft horsepower.
Total steam per hour..... 35,100 pounds
Principal auxiliaries (= 118 horsepower) steam per hour.... 6,200 pounds
Miscellaneous auxiliaries—steam per hour..... 2,500 pounds
(including air removal from condenser)
Total steam generated per hour..... 44,700 pounds
Total heat in steam above 32 degrees F..... 1,181.9 British thermal units
Temperature of condensate—90 degrees F.
Heat of liquid in condensate..... 58.1 British thermal units
Heat added per pound of feed to make steam... 1,123.8 British thermal units
British thermal units consumption $\frac{1,123.8 \times 44,700}{3,000} = 16,750$ per shaft h'power
Assuming fuel oil of 18,500 British thermal units per pound, and a boiler room efficiency of 78 percent, the fuel consumption would be—
 $16,750 \div (18,500 \times 0.78) = 1.16$ pounds per shaft horsepower

Example 1-a

Conditions the same as in Example 1 except all auxiliaries are reciprocating with the exception of the blowers. Then the auxiliary steam consumption would be increased to about.....15,000 pounds per hour
The fuel consumption would be.....1.31 pounds per shaft horsepower hour

Example 2—Steam Driven Auxiliaries—Fig. 2

Feed heated to 235 degrees F., excess exhaust to condenser.
Steam pressure—200 pounds gage—98 percent quality.
Vacuum—28½ inches.
Shaft horsepower—3,000.
Steam consumption—main turbines—11.7 pounds per shaft horsepower hour.
Total steam, pounds per hour..... 35,100
Principal auxiliaries (118 horsepower)..... 6,200
Principal auxiliaries steam per hour, pounds..... 6,200
Miscellaneous auxiliaries steam per hour, pounds..... 2,500
Air ejectors steam per hour, pounds..... 900
Total steam per hour, pounds..... 44,700
Total heat in air ejectors—steam above 32 degrees F., 1,100 British thermal units
(Note—The ejectors have done work in removing air from the condenser.)
Temperature of condensate 90 degrees F.
Heat of liquid..... 58.0 British thermal units
Heat in each pound of ejector steam available for heating 1,041.9 British thermal units
Total British thermal units in ejector steam $1,041.9 \times 900 = 938,000$ British thermal units per hour.
Rise in feed temperature $= \left(\frac{938,000}{35,100 \times 900} \right) = 26$ degrees F. (See note.)
Temperature of feed and filter tank—116 degrees F.

British thermal units needed per pound of feed to heat to 235 degrees F. =
 $235 - 116 = 119$.

$$\text{Total exhaust steam needed} = \frac{36,000 \times 119}{1,000} = 4,280 \text{ pounds}$$

Note—It is assumed that each pound of exhaust steam condensed at 235 degrees F. will give up 1,000 British thermal units.

This will leave $8,700 - 4,280 = 4,420$ pounds of exhaust steam not usable in the heater, and part will go to the condenser and part will be used to heat the first part in the feed heater. The error made in assuming 1,000 British thermal units given up in condensing in either heater or condenser will be very small; therefore, if X = amount of steam to condenser, $4,420 - X$ equals the amount used to heat it from 90 degrees to 235 degrees F. This requires 145 British thermal units per pound, or

$$X \times 145 = (4,420 - X) \times 1,000 \text{ or } 1,145 X = 4,420,000$$

or $X = 3,860$ pounds to the condenser and 560 pounds used in the heater.

Whether the steam condensed in the heater goes to the feed and filter tank, raising the temperature there, or whether it mixes directly with the feed, will make so little difference in this heat balance that it is assumed to mix with the feed.

Total heat in steam above 32 degrees F. 1,181.9 British thermal units
 Heat in liquid of feed at 235 degrees F. 203.6 British thermal units

Heat added to feed per pound to make steam. . . 978.3 British thermal units

British thermal units consumption =

$$\frac{978.3 \times 44,700}{3,000} = 14,580 \text{ pounds per shaft horsepower}$$

Fuel consumption = $14,580 \div (18,500 \times 0.78) = 1.01$ pounds per shaft horsepower hour.

(Note—There being an excess of exhaust steam for feed heating, the final result would be the same if the heating from the ejector steam were calculated as if occurring in the feed heater.)

Fig. 3

Example 3—Steam Driven Auxiliaries—Fig. 3

Feed heated to 235 degrees F.—excess exhaust to main turbine.
 Steam pressure—200 pounds gage—98 percent quality.
 Vacuum—28½ inches.

Shaft horsepower—3,000.

Total auxiliary exhaust—pounds per hour—9,600 pounds.

Excess auxiliary exhaust admitted at point of main turbine where pressure is 18 pounds absolute. Then for adiabatic expansion—

British thermal units at 215 pounds absolute 98 percent quality. 1,181.9

British thermal units at 28½ inches vacuum. 834.8

347.1

British thermal units at 18 pounds absolute. 1,003.7

British thermal units at 28½ inches vacuum. 834.8

168.9

Therefore, steam entering the main turbines at 18 pounds absolute will do

approximately $\frac{168.9}{347.1} = 49$ percent of the work of high pressure steam.

The error in assuming that one pound of exhaust steam will do work in the low pressure end, which will save one-half pound of high pressure steam, is very small.

Let X = the pounds of auxiliary exhaust steam per hour which passes into the main turbine:

Then $9,600 - X$ is the amount used in heating feed and $\frac{X}{2}$ is the amount

of high pressure steam saved. Total steam to condenser equals high pressure steam or $3,000 \times 11.7 - \frac{X}{2} = 35,100 - \frac{X}{2}$, plus the exhaust steam ad-

mitted to the turbine or X pounds or the total condensate is

$$\left(35,100 - \frac{X}{2}\right) + X = 35,100 + \frac{X}{2}$$

The British thermal units per pound of feed needed to heat from a condensate temperature of 90 degrees to 235 degrees F. = 145 or the exhaust steam needed for heating equals

$$(9,600 - X) = \left(35,100 + \frac{X}{2}\right) \times 145 \div 1,000$$

(1,000 British thermal units is the heat given up in condensing each pound of exhaust.)

Therefore, $X = 4,200$ and $9,600 - X = 5,400$.

The total main turbine high pressure steam = $35,100 - \frac{4,200}{2} = 33,000$

The total auxiliary steam per hour = ... 9,600

Therefore, the total feed in pounds per hour = ... 42,600

From Example 2, the heat required per pound of feed to generate steam = 978.3 British thermal units;

and the British thermal units consumption = $\frac{978.3 \times 42,600}{3,000} = 13,900$

pounds per shaft horsepower.
 Fuel consumption equals $13,900 \div (18,500 \times 0.78) = 0.96$ pound per shaft horsepower hour.

Example 3-a

Conditions the same as in Example 3 except that as in Example 1-a all auxiliaries, with the exception of the blowers, are reciprocating.
 Total auxiliary exhaust—pounds per hour = 15,000.

$$\text{Then } (15,000 - X) = \left(35,100 + \frac{X}{2}\right) \times 145 \div 1,000$$

or $X = 9,250$ pounds and $15,000 - X = 5,750$ pounds.

Total main turbine high pressure steam = $35,100 - \frac{9,250}{2} = 30,475$

Total auxiliary steam = ... 15,000

45,475

Therefore, fuel consumption equals 1.03 pounds per shaft horsepower hour.

Fig. 4

Example 4—Circulating Pump and Boiler Feed Pump Driven from Main Turbine—Other Auxiliaries Separately Steam Driven

Total shaft horsepower to propeller = 3,000.

Additional shaft horsepower to drive circulating and boiler feed pumps = 80.

(Note—Allow 5 shaft horsepower additional for drive of boiler feed pump.)

Total auxiliary exhaust = 5,800 pounds.

Then, as in Example 3:

$$\text{High pressure steam to main turbine} = 3,080 \times 11.7 - \frac{X}{2}$$

equals $36,050$ pounds — $\frac{X}{2}$ and total exhaust

equals $36,050$ pounds + $\frac{X}{2}$ pounds per hour.

$$\text{or } (5,800 - X) = \left(36,050 + \frac{X}{2}\right) \times 145 \div 1,000$$

or $X = 535$ pounds and $5,800 - X = 5,465$ pounds.

The total main turbine high pressure steam = $36,050 - \frac{535}{2} = 35,782$

The total auxiliary high pressure steam = ... 5,800

Therefore, the total feed in pounds per hour = ... 41,582

The British thermal units consumption = $\frac{978.3 \times 41,582}{3,000} = 13,560$ per

shaft horsepower,
 and fuel consumption = $13,500 \div (18,500 \times 0.78) = 0.94$ pound per shaft horsepower hour.

Fig. 5

Fig. 6

CONDITIONS ASSUMED IN EXAMPLES

It will be seen that in all of the above examples the conditions outlined in arrangement "A" are only approximated, as it is impracticable to have any electrically driven auxiliaries receiving their power from the main power unit. Example 4 approaches most nearly to the conditions of arrangement "B" and in the arrangements suggested for Example 3 and 4, the automatic valve for admission of the auxiliary exhaust steam to the main unit is quite desirable as there will always be some steam going through this connection. Such a valve is shown in Fig. 5 and its arrangement in the ship, in Fig. 6.

The excess steam from the auxiliary exhaust line would enter at G, Fig. 5, passing out to the turbine at L. A small amount of steam leaks past piston J and its pressure is regulated by the relief valve H, which can be set to any desired pressure. Steam entering at G will tend to build up a pressure under piston J and will cause it to lift until the pressure in G balances the pressure maintained by the relief valve when the piston J will remain stationary, allowing the steam to flow through the ports indicated to L irrespective of the pressure in L as long as it is below the pressure at the inlet G.

The mechanism shown on the top of the valve is connected to the maneuvering valve and to an overspeed governor so that in case it is necessary to shut off steam to the main unit, this automatic "constant pressure valve" will be shut at the same time the main steam inlet is shut, allowing the excess steam to go direct to the main or auxiliary condenser through a suitable relief valve which is set at a higher pressure than is desired in the exhaust line normally.

Examples 1 to 3 show how the fuel consumption of the ship has been reduced 17½ percent by the method of feed heating, using the same equipment of main and auxiliary units. Example 4 shows how a further reduction of 3 percent in total fuel can be effected by driving certain of the auxiliary units directly from the main power unit.

It might, of course, be desirable to extend the arrangement suggested in Example 5 so as to approximate the conditions of arrangement "D," in which all the auxiliaries could be driven from the main unit, the feed heating being

accomplished by bleeding steam from the main turbine and with such an arrangement, if it were possible, a fuel consumption of 0.845 pound per shaft horsepower hour could be obtained. Such an arrangement would be too complicated and, of course, in the case of many auxiliaries, it would be entirely impracticable to drive them directly as such an arrangement necessitates that most of the auxiliaries be capable of being operated when the main unit is shut down and this would run into excessive duplication.

It is possible, however, to employ arrangement "E" and with the modern development of electrical apparatus, there seems to be no reason why such a drive for all of the auxiliaries, the driving motor receiving its power from a central generating unit, cannot be successfully employed. Example 5 indicates the economy of such an arrangement.

Example 5—All Auxiliaries Motor Driven Except Air Ejector

Motors supplied with power from a two-stage turbine driven generator. Steam bled from the exhaust of the first stage into a secondary feed heater and the turbine exhausting into a primary feed heater with the excess going to the main turbine. See Fig. 4.

Total auxiliary power (see Table 1), 152 horsepower. Assuming 80 percent average motor efficiency, the load on the generator will be 142 kilowatts.

(200 kilowatt generating sets would be used to allow a margin of power.)

First stage of turbine, inlet pressure, pounds per square inch absolute... 155

First stage of turbine, exhaust, pounds per square inch absolute... 65

Total British thermal units available for work... 67.5

Exhaust pressure of turbine... 25 pounds absolute

Total British thermal units available for work from 155 absolute to 25 pounds absolute... 135

Therefore, first stage does about 50 percent of the total work or each pound of steam bled from first stage requires one-half pound to be added to maintain the required power.

Steam consumption complete unit in pounds per kilowatt hour... 50

Total steam, if no steam bled = 50 × 142 = 7,100 pounds per hour

Steam per hour from ejector = 900

Total (no bleeding) ... 8,000 pounds per hour

Temperature of steam at 65 pounds absolute = 298 degrees F.

Let X = exhaust steam to main turbine.

Y = steam bled from first stage of auxiliary turbine.

$\frac{Y}{2}$ = amount of high pressure steam added to make up for bleeding.

then $\left(35,100 + \frac{X}{2} \right)$ = pounds steam per hour (see Example 3) to condenser.

$\left(8,000 - \frac{Y}{2} \right)$ = pounds steam per hour exhausted from auxiliary turbine and ejector.

Assume primary heater heats the feed from 90 degrees to 235 degrees F., and the secondary heater from 235 degrees F. to 298 degrees F.

Then the heat added in primary heater

$$= \left(35,100 + \frac{X}{2} \right) \times 145 = (5,090,000 + 72.5 X) \text{ British thermal units per hour.}$$

$$\text{The steam used for this} = \left(8,000 - \frac{Y}{2} \right) - X$$

$$\text{or } \left(8,000 - \frac{Y}{2} \right) \times 1,000 - 1,000 X = 5,090,000 + 72.5 X$$

or X = amount of exhaust steam to main turbine = $2,710 - 0.466 Y$ pounds per hour.

$$\text{The total feed to secondary heater} = \left(35,100 - \frac{X}{2} \right) + 8,000 - \frac{Y}{2} = 43,100 - \frac{(X + Y)}{2}$$

$$\text{The heat added in secondary heater} = \left[43,100 - \frac{(X + Y)}{2} \right] \times (298 - 235) = 2,715,000 - (X + Y) = 31.5$$

$$\text{or } 1,000 Y = 2,715,000 - 31.5 (X + Y), \text{ but } X = 2,710 - 0.466 Y$$

$$1,000 Y = 2,715,000 - 31.5 (2,710 + .534 Y) = 2,629,600 - 16.8 Y$$

$$Y = 2,585 \text{ pounds}$$

$$X = 1,450 \text{ pounds}$$

$$\text{Total steam to main unit} = 35,100 - \frac{X}{2} = 34,375 \text{ pounds per hour}$$

Total steam to auxiliary turbine

$$\text{and ejector} = 8,000 + \frac{Y}{2} = 9,293 \text{ pounds per hour}$$

$$\text{Total feed at temperature of 298 degrees F.} = 43,668 \text{ pounds per hour}$$

British thermal units above 32 degrees per pound of steam..... 1,181.9

British thermal units above 32 degrees per pound water at 298 degrees F. 267.8

British thermal units added to feed per pound of steam..... 914.1

$$\text{The British thermal unit consumption} = \frac{914.1 \times 43,668}{3,000} = 13,300$$

$$\text{Fuel consumption equals } 13,300 \div (18,500 \times 0.78) = 0.92 \text{ pound per shaft horsepower hour.}$$

Note—Peabody's Steam Tables were used for these calculations.

By the use of a single pass condenser and a propeller type circulating pump, the power needed for this unit could be reduced 40 percent, or from 60 to 36 horsepower, and by careful proportioning of other auxiliaries it might be possible to reduce the auxiliary power from 152 horsepower to 115.

Example 5-a

Total auxiliary power..... 115 horsepower
Generator load 108 kilowatts
(150 kilowatt generating sets could be used.)

Auxiliary turbine designed as in Example 5 as to stage pressures, etc.

Total steam, if no steam bled = $51 \times 108 = 5,500$ pounds per hour

Ejector 900 pounds per hour

Total 6,400 pounds per hour

then as in Example 5—

$$\left(6,400 - \frac{Y}{2} \right) \times 1,000 - 1,000 X = 5,090,000 + 72.5 X;$$

$$X = 1,220 - 0.466 Y$$

$$\text{Feed to secondary heater} = 35,100 - \frac{X}{2} + 6,400 - \frac{Y}{2} = 41,500 - \frac{X + Y}{2}$$

The heat added in secondary heater

$$= \left(41,500 - \frac{X + Y}{2} \right) \times (298 - 235) = 2,610,000 - 31.5 (X + Y)$$

$$\text{or } 1,000 Y = 2,610,000 - 31.5 (1,220 + 0.534 Y) = 2,571,600 - 16.81 Y$$

$$Y = 2,530 \quad X = 40 \text{ pounds (or practically nothing)}$$

In other words, the auxiliary exhaust is just sufficient to heat the feed by use of two stage heating.

Total steam to main unit = 35,080 pounds per hour

Total steam to auxiliary turbine

$$\text{ejector} = 6,400 + \frac{Y}{2} = 7,665 \text{ pounds per hour}$$

Therefore, total feed at temperature of 298 degrees F. 42,745 pounds per hour

British thermal units added per pound of feed — 914.1

British thermal units consumption = 13,000 per shaft horsepower hour

and fuel rate = 0.9 pound per shaft horsepower hour.

It is interesting to note the result if only the primary heater were employed, using the same turbine and auxiliaries as in Example 5.

Total auxiliary exhaust..... 8,000 pounds per hour

$$\text{then } 8,000 - X = \left(35,100 + \frac{X}{2} \right) \times 145 \div 1,000$$

$$X = 1,875 \text{ and } 8,000 - X = 6,125$$

Total high pressure steam to main turbine = 34,163 pounds per hour

Total auxiliary steam..... 8,000 pounds per hour

Total feed 42,163 pounds per hour

British thermal units rate = 13,750.

Fuel consumption = 0.955 pound per shaft horsepower hour or 5 percent higher for the same equipment, but not employing two stage heating.

ELECTRIC DRIVE AUXILIARIES

While the use of steam driven auxiliaries has been considered necessary in the past, this idea has been undergoing modification in land power plants. The steam driven unit used to be considered as the most reliable and, while the various units were usually small and uneconomical, it was generally considered that this was unimportant and that since the exhaust steam was either condensed in a feed-water heater or did work in the main turbine, that the actual economy of the unit made no difference. As has been pointed out, however, there may be a big difference in the overall results, as with a more economical drive, less steam would be required to produce the auxiliary power with the saving in total fuel as pointed out above. At the present time, however, electric motors and their circuits are probably even more reliable than the small steam driven units and can be counted on to maintain their functions with less danger of stoppage or interruption. This is certainly true in land practice and will undoubtedly become equally true in marine practice as waterproof motors, wiring and controls are more fully developed.

For the vital auxiliaries the arrangement "F" with both motor and steam turbine drive, should be employed, or duplicate steam driven units should be installed. In the case of the circulating pump, the dual drive of motor and turbine would be suitable. For the feed pump and fuel oil pump, a stand-by steam driven unit would probably be chosen. Duplicate condensate pumps, each with motor drive, would be satisfactory for the main condenser, and these units could be shut down for a reasonable length of time without jeopardizing operation. The same is true of lubrication oil pumps and most of the auxiliaries.

Care must, of course, be taken to insure against interruption of electric circuits and the control of the vital engine room auxiliaries should be grouped together as separate as possible from the circuits for the general ship service. Circuit breakers or other protective devices on the general power and lighting circuits should be more sensitive than those for the vital auxiliaries and it is not improbable that automatic interrupting devices would be eliminated from these latter circuits. Where the total power is sufficient, it is desirable to keep the generating units for the vital auxiliaries separate from those for the general ship's circuits. Where the power is too small, the bus for the one could be connected to the generator without automatic circuit breakers, while the bus for the other general circuit could be protected by such breakers.

While the question may be raised that the improvement of efficiency shown by the various arrangements discussed may be offset by other conditions, it must be remembered that the relative gains indicated will be realized, although it may be difficult to actually measure them in a comparison of any actual installations. Thus, the installation which should show a fuel consumption of 0.92 pound per shaft horsepower hour may be handicapped by poor boiler room efficiency and actually have a poorer consumption than should be given by Example 3, which might in practice have a higher boiler room efficiency. If, in Example 3, the boiler room efficiency were 80 percent, the fuel consumption would be 0.94 pound per shaft horsepower hour, while, if in Example 5, the boiler room efficiency were 80 percent instead of 78 percent, the fuel consumption would be 1.11 pounds per shaft horsepower hour. On the other hand, the rate of 0.94 would have been reduced to 0.90 if the change in auxiliary drive and feed heating outlined. A common reason for not maintaining the highest possible attainable efficiency of a given plant is that it is difficult

actually measure the benefits or the gains derived from improvements because of other changes taking place which tend to offset the gains and it is, therefore, sometimes advisable to listen to the "theorists" rather than to the so-called "practical man" who can only believe what he can measure with a rule or scale.

IMPORTANCE OF AUXILIARY ECONOMY

The importance of auxiliaries in obtaining economical operation cannot be too strongly emphasized. They should be so maintained as to give their best possible performance at all times. Mere ability to operate without stopping is not enough. A recent test of a small engine driven lighting set supposed to operate on less than 100 pounds of steam per kilowatt hour, showed an actual consumption of over 300 pounds per kilowatt hour. The engine ran fairly well, but leaky pistons, changes in valve settings, etc.,

has been referred to above, the use of an economizer to further heat the feed from 300 degrees to 350 degrees and the use of air heaters placed in the gases after they have been passed through the economizers would result in very low stack temperatures with a definite gain in overall economy. It must be realized that the art of building economizers is progressing and many of the problems in the past which have been found difficult are now solved and such pieces of apparatus can no longer be considered impracticable, even though their cost may be formidable.

With the use of such equipment, the assumed boiler efficiency of 78 percent might be readily increased to 87 percent and our fuel consumption in Example 5 would be reduced from 0.92 to 0.823 pound per shaft horsepower hour.

The use of high steam pressure and superheats has been referred to and it is of interest to study along the same line of the preceding examples what fuel consumptions could be expected in such an installation. For this study, a boiler pressure of 600 pounds gage, superheating the steam 200 degrees F. has been assumed. Superheaters, economizers and air heaters would all be employed and the auxiliaries would all be motor driven as in Example 5. The main turbine would be divided into three portions, consisting of a high pressure turbine, intermediate pressure turbine and low pressure turbine. The high pressure turbine would take steam at 500 pounds absolute (allowing a 115-pound drop between boiler and turbine) and would exhaust to a pressure of 160 pounds absolute. The intermediate pressure turbine would take steam at this pressure and exhaust at 13 pounds absolute, and the low pressure turbine would exhaust to a 28½-inch vacuum as previously assumed. (Other pressure distributions may be found to be even more economical, depending on the actual installation.)

caused the enormous increase in steam consumption. Similarly, other pumps and engines can soon deteriorate so that the total auxiliary consumption is excessive and the condition assumed in Example 2-a is a real one.

Occasional tests of the steam consumption of the various auxiliaries while in port is not only practicable, but well worth while.

MAINTAINING A HIGH VACUUM

There are, of course, many other departments in which improvements in efficiency can be realized by care and knowledge of the fundamental characteristics of the apparatus. This is particularly true in relation to the condenser and the vacuum maintained under varying conditions of sea water temperature, etc. A tight vacuum system and clean tubes, both inside and out, are well repaid in maintenance of high efficiency. The accumulation of oil and grease on the surface of the condenser tubes may readily give a loss in vacuum of 1 inch and this will affect the overall efficiency from 4 to 6 percent. One inch of vacuum may readily be lost by air leaks and an equal amount by logging up of the circulating cooling water system, particularly the condenser tubes.

WASTE GAS AIR HEATERS

Economizers have been suggested, too, and what is perhaps more common in ships, the use of air heaters, in which the waste gases preheat the air to the burners. Where higher boiler pressures are to be employed, it is possible that both economizers and air heaters may prove advantageous. With the high temperature feedwater heating that

Fig. 7

The auxiliary power generating unit and the ejector would take their steam from the exhaust of the high pressure turbine and would in turn exhaust through a feedwater heater to the inlet of the low pressure turbine (Fig. 7). There would also be a feedwater heater in parallel with the inlet of the auxiliary turbine, taking its steam from the exhaust of the main high pressure turbine. The auxiliary turbine would be equipped with an automatic valve, which in case of shutting down on the main unit, would admit boiler steam directly and thus prevent any interruption of service due to sudden maneuvering of the main unit. This valve could also be actuated by hand so that during maneuvering of the main unit, the auxiliary unit would be operated independently.

Example 6 shows the probable consumption from such an arrangement:

Example 6—Fig. 7

600 pounds boiler pressure, 200 degrees F. superheat.
Auxiliaries driven by motors.
Auxiliary power generated by turbine receiving steam from main unit at end of first stage, exhausting to heater and inlet of low pressure stage.
Two-stage feed heating.
Allow 115 pounds drop to main turbines.
Inlet pressure, main turbine, pounds per square inch absolute, 500.
Total heat in steam above 32 degrees F.—British thermal units per pound, 1,352.
Exhaust of high pressure turbine, pounds per square inch absolute, 160; temperature, 364 degrees F.
Exhaust of intermediate pressure turbine, pounds per square inch absolute, 13; temperature, 236 degrees F.
Vacuum in low pressure turbine exhaust, 28½ inches; temperature, 92 degrees F.
Percent total work done in high pressure = 25 or ¼ of total.
Percent total work done in low pressure = 33⅓ or ⅓ of total.
Steam consumption—main unit with no bleeding or heating, 8.10 pounds per shaft horsepower hour
or a total of $8.10 \times 3,000 = 24,300$ pounds per hour.
Auxiliary unit taking steam at 160 pounds absolute (and 160 degrees superheat)

exhausting to 13 pounds absolute will have a steam consumption of 31 pounds per kilowatt.

Total steam consumption of one turbine = $105 \times 31 = 3,250$ pounds per hour.

(Note—Amount of circulating water greatly reduced.)

Condensing type ejector..... 450 pounds per hour

Total 3,700 pounds per hour

Let X = steam per hour from auxiliary turbine exhaust not used in primary heater into low pressure inlet of main turbine.

Let Y = steam per hour bled from intermediate pressure inlet to auxiliary turbine and secondary heater,

then $3,700 - X$ = amount of steam used in primary heater.

$Y = 2,700$ amount of steam used in secondary heater.

$$\text{High pressure steam to main turbine} = 24,300 + \frac{3Y}{4} - \frac{X}{3}$$

(For every pound bled out at 160 absolute $\frac{3}{4}$ pound must be added to go through whole of main unit to do the work required.)

$$\text{Steam to condenser} = 24,300 - \frac{Y}{4} + \frac{2X}{3}$$

The primary heater heats from 90 degrees to 206 degrees F. for 116 degrees,

$$\text{then } 1,000 (3,700 - X) = \left(24,300 - \frac{Y}{4} + \frac{2X}{3}\right) \times 116$$

$$\text{or } X = 816 + 0.027Y$$

Feed to secondary heater equals steam to condenser plus

$$3,700 - X \text{ equals } 28,000 - \frac{Y}{4} - \frac{X}{3}$$

The secondary heater heats from 206 degrees to 364 degrees F. = 158 degrees,

$$\text{then } 1,000 (Y - 3,700) = \left(28,000 - \frac{Y}{4} - \frac{X}{3}\right) \times 158$$

$$Y = 7,820 \quad Y - 3,700 = 4,120 \text{ pounds}$$

$$X = 1,027 \quad 3,700 - X = 2,673 \text{ pounds}$$

Total steam to high pressure unit = $24,300 + 5,860 - 342$ equals 29,818 pounds per hour.

The total heat of the steam = ... 1,352 British thermal units

The temperature of feed 364 degrees.

The British thermal units of liquid in feed — ... 336

Heat added to make steam = ... 1,016 British thermal units

British thermal unit rate = $29,818 \times 1,016 \div 3,000 = 10,100$

With economizers, air heaters and superheaters, a boiler efficiency of 87 percent can be counted on.

Therefore, the fuel consumption based on a heat value of 19,500 British thermal units per pound equals

$$10,100 \div (19,500 \times 0.87) = 0.595 \text{ pound oil per shaft horsepower hour.}$$

CHAMBER OF COMMERCE MEETING.—At the eleventh annual meeting of the Chamber of Commerce of the United States, to be held in New York, May 7 to 11, "Transportation in all its phases in the United States" and "Europe's Affairs" will be the main topics of discussion.

Comparison of Fuel Costs With Coal and Oil Fired
Steamers Explains Growth of Motorship Building in Europe

By Our Special London Correspondent

THERE still remains a suspicion in the minds of many shipowners that a large proportion of the statements made relating to the economies which it is possible to effect by employing oil engines for ship propulsion are not founded on facts but are mere estimates which may, or may not, be borne out in actual practice. In dealing with the subject, it is therefore of the first importance to give some information relating to the fuel consumption of corresponding steam and motorships, attained during the course of normal service and under similar conditions.

It has to be borne in mind that it is not a sufficient inducement to the shipowner to become the advocate of the oil engined vessel merely to show a certain reduction in fuel bill as compared with the steamer. The initial cost of a motorship is considerably higher than that of one fitted with a steam engine, and the economies effected in operation must therefore be of sufficient magnitude to wipe off the additional expenditure in the course of a few years. For instance, it will be found that at the present time a good type of 10,000 ton (deadweight) motorship designed for 10½ or 11 knots at sea will cost between £130,000 and £140,000 whereas a steamer can be obtained for about £100,000. Therefore, there will be little advantage to the shipowner in employing oil engined vessels unless he can be assured of a saving in operating expenses of at least £3,000 annually. Indeed, this amount would

scarcely be a sufficient inducement for adopting the motorship.

FUEL CONSUMPTION RECORDS

In order to elucidate this problem some tables have been

The Shipping Board has in its possession a large number of vessels having good hulls in which inefficient propelling machinery is installed. These ships are of no value as they are but they may be converted into first class motorships under the plans now being developed by Admiral Benson at a cheaper cost than similar vessels could be constructed anywhere else in the world. The difference in first costs between steamers and motorships and the fixed charges thereon have been the principal reasons why motorships have not been developed to a greater extent in this country. But now that good hulls are available for conversion at a price reported to be between \$5 and \$10 a ton shipowners have an opportunity that will never be repeated to acquire vessels that will save them money by materially decreasing their fuel bill and by increasing their freight revenue through larger carrying capacity.

prepared to show the fuel consumption of various types of ships. These details, which are given below, relate to the average speed and daily fuel consumption obtained over long periods, in many cases representing a series of voyages up to a total of 100,000 miles, or two years' operation. In no case are they given for merely short runs or are they the results obtained on trials, and it is a notable fact that in practically every case, the amount of fuel required after a year or two's service is found to be somewhat lower than when the vessel is first placed in commission.

The next table gives a comparison between a steamer and a motorship of almost identical size, tonnage and speed. The figures relating to the steamer are official and are extracted from a paper read in March before the North East Coast Institution of Engineers and Ship-

builders.* This steamer is one of the most economical type afloat, being fitted with steam turbines and double-reduction gearing. A boiler pressure of 200 pounds per square inch is used, and the steam is superheated to 200 degrees Fahrenheit. An ordinary reciprocating engined vessel would have

*"Notes on the Economical Performance of Turbine Installations in Merchant Ships" by T. G. Potts.

Single Screw Cargo Motorship Yngaren, of 9,350 Tons Deadweight, Built and Engined by William Doxford and Sons for Transatlantic Steamship Company, of Gothenburg

a fuel consumption approximately 15 percent higher and, the result given probably represents the best that can be obtained with a steamship of this size. The average speed and consumption relate to 16 voyages, totaling about 50,000 miles.

The motorship, with which comparison is made, is the *Yngaren* and the figures are those given by Mr. Madsen, the superintending engineer of the Transatlantic Company (the owners of the vessel) in a paper before the Institute of Marine Engineers.† In this case, also, the results are those over a number of voyages of long duration.

It will therefore be seen that with the most efficient steamer afloat, the amount of coal consumed is $3\frac{1}{2}$ times the oil required for a motorship of the same size and slightly higher speed. We may therefore assume that with the average class of steamer the amount of coal required is quite four times the oil burned in the Diesel engines of a motorship. It should, perhaps, be added that in this motor vessel bunker oil is utilized, of the same grade as that burned under boilers.

COMPARISON OF FUEL COSTS

The *Yngaren* takes on her oil at the Panama Canal, where the cost is about £2 per ton, giving a daily fuel bill of £21.12.0. The average price for coal throughout the world is about £2 per ton, giving a fuel bill for the steamer of £75.8.0 and showing a saving of £53.16.0 per day in favor of the motor vessel. Even allowing for bunker coal obtained at 30/- per ton, (which is nearly the lowest possible price) the steamer's fuel bill will be £56.12.0 showing a saving of £35, or between £8,500 and £9,000 per annum.

If we make the comparison between oil fired steamers and motorships, the results are equally striking. Some time ago, the Fuel Conservation Committee was authorized by the United States Shipping Board to carry out some trials on the oil fired steamer *President Polk* and her sister ships. These vessels are 502 feet between perpendiculars with a beam of 62 feet, and it was found that the average results showed a speed of 13.9 knots on a daily oil consumption of 89.6 tons.

There are about a dozen motorships of approximately the

FUEL CONSUMPTIONS OF MOTORSHIPS

Motorship	Deadweight, Tons	Aver. Speed, Knots	Daily fuel Consumption, Tons
<i>Bullaren</i>	11,000	10.8	10.90
<i>Falstria</i>	7,500	10.0	8.00
<i>Buenos Aires</i>	9,400	11.0	10.50
<i>Glengyle</i>	10,000	11.5	10.30
<i>Glenary</i>	10,000	11.5	10.68
<i>Lobos</i>	10,000	10.6	10.30
<i>Glenluce</i>	10,000	10.0	10.60

COMPARISON BETWEEN A STEAM AND MOTOR SHIP

	Double Reduction Gearing Turbine Vessel, 200° F. Superheat	Motorship <i>Yngaren</i>
Length	425 feet	420 feet
Beam	55 feet	54 feet
Load draft	25 feet 6¼ inches	25 feet 6 inches
Gross tonnage	5,494	5,247
B.H.P. at sea	2,750	2,700
Speed, knots	11.12	11.2
Fuel Consumption per day, tons	37.7 (coal)	10.8 (fuel oil)

same size and speed now in service, such as the *Glenary* owned by the Glen Line and the *Lochkatrine* and *Lochgo* operated by the Royal Mail Steam Packet Company. Over long voyages, the daily fuel consumption of these vessels works out at 21 tons with a speed of 13 knots. Admitted this is a somewhat lower speed than that of the *President Polk* but the amount of oil consumed is actually less than one fourth of that required in the steamers.

FUEL COSTS AT CURRENT PRICES

It will be agreed from the figures given in the first table that a 10,000 ton motorship with a speed of $10\frac{1}{2}$ or 11 knots will have an average daily consumption of not more than $10\frac{1}{2}$ tons. A corresponding oil fired steamer burns about 30 tons daily. Accepting these figures, an interesting comparison can be made between fuel costs of the two classes of ship, at current prices for fuel oil and Diesel oil.

† "Internal Combustion and Economy," by Tage D. Madsen.

Taking New York as the bunkering port, the quotations for fuel oil and Diesel oil, at the time of writing, are respectively 42/- and 53/- per ton. This gives a daily fuel bill of £64.10.0 for the steamer and £27 for the motorship. In London, the corresponding prices for oil are 65/- and 80/- per ton, so that a steamer bunkering at London would have to pay £97 for its fuel per day, against £42 for a motorship. A coal fired steamer would burn not less than 38 tons daily, and with bunker coal at 32/- and 35/- per ton at New York and London respectively, the daily fuel bill of a vessel bunkering at one or other of these ports would be £61 and £67.

It would seem from these facts that, at any rate for average cases, the additional expenditure on the motorship is well warranted. Each case must necessarily be analyzed on its merits, but it must always be remembered that, owing to the wide radius of action, the motorship can carry sufficient fuel in double bottom tanks for very long voyages and is able to choose the port at which it will purchase fuel. In other words, the motor vessel has better opportunities for obtaining a cheap supply than either the oil fired or coal fired steamer.

MOTORSHIP CAN CARRY MORE FREIGHT

Even when a good margin is allowed in this respect, the

motorship is still able to carry a larger freight than the steamer owing to the reduced weight of the fuel and this is, of course, particularly noticeable in the case of comparisons with a coal fired ship. This fact must not be lost sight of when comparing the prices of steamers and motorships of the same dimensions.

It may be added that in connection with a 22,000 ton motor liner which is now being built by the Fairfield Company for the Union Steamship Company of New Zealand, Mr. Traill, the engineering manager of the building firm, stated that owing to the adoption of internal combustion machinery the passenger accommodation has been increased 18 percent beyond that which would be possible on a steamer of the same size and speed.

It may be asked whether the economies outlined above are not offset to some extent by a larger repair bill in the case of the motor vessel. It may definitely be stated that this is not the case, and that the average motorship has a repair bill little, if any, higher than that of the reciprocating engined vessel and probably a good deal lower than the cost involved with a geared turbine ship.

No better instance of this can be afforded than the results which have been publicly announced concerning the operation of the *William Penn*, the repair bill of which, for a whole year's service, only amounted to something like \$100.

British Shipyards Get String of New Contracts

Individual Shipowners Going Ahead—Both the Shipbuilding and Shipbreaking Outlooks Are Getting Much Brighter

By W. H. Wendon

THE past month has been characterized by a remarkable divergence of opinion as to whether the shipping depression has really touched bottom, or whether that deplorable condition has yet to arrive. One is, indeed, tempted, the risk of being dubbed "slangy," to express the conviction that shipowners—and in this connection I include shipbuilders and engineers—in the words of the popular song: "I don't know where they are." Whatever the immediate or distant future may hold, however, there is no denying the fact that shipping has of late received a decided fillip as regards exports, but, so far as one is able to judge, this is almost entirely due to the stoppage of German mining on the Ruhr, following the occupation by the French. This branch of the shipping trade is, therefore, experiencing a "boom" time—the moment; but the experts are generally agreed that, as soon as reconciliation is reached on the Ruhr, the influx of orders will be suspended, with a consequent relapse in the shipping trade. Briefly, then, the effect of the Ruhr situation has been to create a sudden artificial demand to fill the gap left open by the cessation of production in the great German coal area. The result has been an abnormal rise in the price of British coal, and the advantages accruing to shipowners have been to some extent offset by the increased cost of bunkers.

IT TIME FOR SHIPOWNERS TO ORDER NEW VESSELS?

The principal point of discussion between shipowners and shipbuilders at the moment, however, is in regard to the question. Have shipbuilding costs fallen to an irreducible minimum? Accordingly, can shipowners now step in and order vessels whereas formerly they had to tread warily in this delicate matter? Mr. J. C. Gould, who occupies the rather unusual position of being shipowner, shipbuilder and engineer,

believes beyond the shadow of a doubt that the end of the shipping depression has been reached, that, in fact, it has been passed, and that the shipping trade is now on the upward trend as regards cheaper constructive costs. Wages, he feels, cannot be further reduced, and he is convinced that the price of steel can go no lower. Summed up, therefore, his conviction is that shipowners are only wasting time if they now refrain from ordering new tonnage.

Without for one moment attributing to Mr. Gould the art of being two-faced, one has obviously to bear in mind that, in expressing his views in this manner, he may be—I do not suggest he is—obsessed by the knowledge that he is a shipbuilder, and, therefore, that from the point of view of a shipbuilder, the educating of shipowners into a contracting frame of mind is by no means undesirable. Anyhow, time alone can prove the correctness of his forecast that pronounced improvement in trade is only a few months off. Incidentally, Mr. Gould is not alarmed at the possibility of America throwing seventeen hundred ships on the market, because, in his opinion, "half these ships could never be operated, and the balance would never be operated at a profit."

In contrast to Mr. Gould's optimistic utterances, it is interesting, if not instructive, to note that Mr. Lawrence Holt, a director of the Blue Funnel Line (Messrs. Alfred Holt and Company, Liverpool), speaking at the launching of the twin-screw geared turbine steamer *Patroclus*, placed in the water for his company, stated that he regards this vessel not as a commercial proposition, but as representing an act of faith in the future, she having been built out of the profits of the past in the hope that better times will come. Mr. Holt appreciates what shipbuilders have accomplished in the matter of reducing costs of construction, but says that, even at present reduced costs, shipbuilding cannot possibly flourish. His

views are, therefore, in direct contradiction to those of Mr. Gould, who, as I have indicated above, considers that it is out of the question for shipbuilding costs to be further reduced.

DIESEL ENGINE PRICES WILL HAVE TO BE REDUCED

Sir Walter Runciman, chairman of the reorganized Moor Line (the original Moor Line, it will be recalled, was voluntarily wound up after distributing a handsome return to the shareholders consequent on the sale of the fleet at "boom" values), is more than a little inclined to draw the same conclusions as Mr. Holt, for the Moor Line is ready to give more orders when, in the opinion of Sir Walter Runciman and his co-directors, "prices come again to an economic level." The Moor Line directors, be it added, have also come to the conclusion that the original price of Diesel or other internal combustion engines will have to come much nearer the price of steam engines before they can regard the change as commercially justified.

SHIP BREAKING OUTLOOK BRIGHTER

Apropos the general shipping situation, the question of scrapping obsolete or semi-obsolete merchant vessels is again to the fore, and, as was the case two years ago, the prime mover in the discussion is Lord Kysant, better known, perhaps, as Sir Owen Phillips, which was his title until he was recently elevated to the peerage. When Lord Kysant, in his then capacity of President of the Chamber of Shipping of the United Kingdom, broached this subject two years ago, he urged the necessity of shipowners doing everything in their power to revive the ship breaking industry, which during the war had passed out of existence, consequent on every vessel, whatever her age or character, being required to offset the effects of the submarine sinkings.

Two years ago, however, the cost of breaking up a vessel was greater than the value of the material when scrapped. Lord Kysant was then, as he himself describes it, thought to be "speaking in the wilderness," but times have changed, and it is understood that this old trade is now reviving, if not in the United Kingdom, at least in other countries. A beginning has already been made in the breaking of vessels, but the presence in harbors all over the world of idle vessels of varying ages and in doubtful condition is obviously a factor on which the adherents of the break-up policy wish shipowners generally to ponder.

HIGH BOOK VALUES PREVENT SCRAPPING

It is a fact, however, that, although there is, under the British flag, a large amount of tonnage which, by reason of age, must be considered as fit for the scrap heap, there is very little offering for sale to ship breakers. The reason, however misguided, is not far to seek: It lies in the fact that the many boats acquired when prices were high still stand in the shipping companies' books at enormous figures, and the owners are not unnaturally reluctant to sell the vessels at knock-down prices, thus automatically writing off vast capital sums. They prefer, at all events for the present, to hold the vessels in the hope that the not too distant future may produce a general "boom," if only in miniature, when their losses would be mitigated.

STRING OF NEW CONTRACTS PLACED

It must not be imagined from the foregoing paragraphs that the air of gloom pervading the shipping atmosphere has dispelled the desire of shipowners, as individuals, to augment their fleets. Indeed, the reverse is the case. The past month has seen the placing of a string of new orders, ranging from large motor liners to the humble coaster. Major interest, perhaps, attaches to the contract placed by the Swedish-American Line, of Gothenburg, with Sir W. G. Armstrong, Whitworth and Company, of Newcastle, for a motor liner of

17,000 tons gross, and to have accommodation for 1,600 first, second and third-class passengers.

This vessel, which is intended for the company's passenger and cargo service between Gothenburg and New York, will be propelled by twin-screws driven by double-acting four-cycle motor engines of an entirely new type, developing 1,500 shaft horsepower, and intended to give the vessel a speed of $17\frac{1}{4}$ knots. The motors, which are the first of this type to be built, will be delivered by Messrs. Burmeister & Wain, of Copenhagen, and are considered to be the greatest advance in Diesel engineering hitherto entered upon.

Then, Messrs. Vickers, of Barrow, have received from the Donaldson Line, of Glasgow, an order to build a cargo and cattle liner, to have a length of 400 feet and to carry nearly 8,000 tons of cargo. There will also be provision for several hundreds of store cattle. This boat will operate between Liverpool, Glasgow and Canadian ports, and will be propelled by internal combustion engines of the Vickers' standard patent four-cycle solid injection type, developing about 3,000 horsepower upon a single shaft. This Donaldson liner will, when completed, be the first Diesel cattle and cargo liner on the North Atlantic.

JAPANESE CONTRACT FOR MOTORSHIPS

Other vessels to be built include two motor cargo boats each of about 10,000 tons deadweight, contracted for by Nippon Yusen Kaisha. One is to be built by Messrs. Harland and Wolff in their Govan (Glasgow) shipyard, and the other by Messrs. Lithgows, of Port Glasgow. The Furness Shipbuilding Company, of Haverton Hill, are to build a cargo liner of 8,000 tons for London shipowners. She is to be fitted with Diesel engines of the Sulzer type by Wallsend Slipway and Engineering Company. The design power is 1,800. Messrs. Andrew Weir and Company, of London and Glasgow, have ordered three cargo vessels from Messrs. Harland and Wolff, of Govan. They will have internal combustion engines, constructed at Messrs. Harland and Wolff's Diesel engine works at Glasgow. Messrs. William France, Fenwick and Company, Ltd., London, have ordered four steamers of about 3,300 tons each, two from Messrs. Vickers and two from Sir James Laing and Sons, Sunderland. The Blythswood Shipbuilding Company, Glasgow, are to build two cargo steamers, of 8,000 tons deadweight each, for Messrs. R. S. Dalgliesh, Ltd., Newcastle. The contract price is stated to be £9 per ton. Messrs. William Cory and Son, London, have ordered a 3,400-ton deadweight self-trimming collier from Messrs. Swan, Hunter & Wigham Richardson, Newcastle, and Messrs. Barclay, Currie and Company, Glasgow, are to build a large cargo vessel to be fitted with double-acting Diesel engines, for London owners. Last, but not least, Mr. William L. Roxburgh, of the Coast Lines, Ltd., Liverpool, has contracted for four steamers of 250 feet in length, and has stated to be about to place contracts for another sixteen vessels of this size, in addition to a large cargo steamer. In analyzing the above list of new contracts it is as well to bear in mind that the owners concerned are mostly of the "mushroom" type—here to-day and gone to-morrow—but in nearly every instance are old-established firms or companies. It is safely to be inferred, therefore, that they at least have a certain amount of confidence in the future.

LOSSES ON AMERICAN SHIPS DUE TO FIRE.—The United States Steamboat Inspection Service in its yearly (1921-1922) report shows that 21.4 percent of last year's marine property losses on American ships were due to fire. Consulting the previous reports the toll paid to fire during the past eleven and one-half years amounted to 13.4 percent of all property losses. Excluding our war years in which other losses were abnormal the remaining period charges fire with 15.7 percent.

Fourth British Built Motor Passenger Liner Fitted With Diesel Engines Just Commissioned

New Vessel Is Similar to Steamers Owned By Same Company,
Giving Excellent Opportunity for Valuable Economic Comparisons

By Our London Correspondent

THE development of the motor passenger liner has been one of the most interesting features in British ship-building during the past few years. There are now three oil engined passenger ships in regular service, and although they are not of very large size, the satisfactory nature of their performance has led to orders being placed for motor liners up to over 20,000 tons-gross.

A fourth vessel of the same class has just been commissioned. She is named the *Dumana*, and was built on the Clyde by Barclay, Curle & Company for the British India Steam Navigation Company for their passenger and cargo service between London and Bombay.

She is what may be termed an intermediate class of ship with a speed at sea of just under 13 knots, a cargo carrying capacity of about 11,000 tons, and accommodation for between 130 and 140 first and second class passengers. The three previous liners which have been referred to are the *Adda* and the *Aba* (vessels of 9,000 tons-gross with accommodations for about 330 passengers, engaged on the run between Liverpool and the West Coast of Africa) and the *Domala*, which is very similar to the *Dumana*, and was built for the same owners.

ELECTRIC WINCHES USED

Apart from her machinery, the *Dumana* is a type of ship well known to travelers to the East. The cargo is carried

in three holds forward of the engine room and three aft, served by twelve electric winches, some of three tons' capacity and the others of seven tons.

It is noteworthy that in the majority of the more recent European motorships, electricity is used for operating the winches, as well as for most of the auxiliary machinery in the engine room. Admittedly, this adds somewhat considerably to the first cost, while the weight of the plant is higher than when steam machinery is employed. Nevertheless, the economy in fuel is so large that when ship owners have had experience with both electrical and steam auxiliaries, they seem invariably to prefer the former type. It is stated, for instance, that on the *Dumana* only one-tenth of the amount of fuel will be used for the auxiliaries as compared with that required if the whole of the plant were steam driven.

STRIKING FUEL COMPARISON FOR SIMILAR SHIP

The saloons and passenger cabins in the new ship are arranged on exactly the same lines as in a corresponding steamer. Incidentally it may be mentioned that the owners have several vessels of the same class equipped with reciprocating steam engines and geared turbines. The coal consumption of these vessels usually averages about 70 tons daily, while when oil firing is utilized, the amount of fuel needed is 45 tons. Against this, the motor liner of the same dimensions and slightly higher speed consumes between 17

Motorship *Dumana*, Top Platform Showing Valve Gear

Motorship Dumana, Starting Platform Looking Forward

and 20 tons of oil daily for all purposes, the former figure being usually attained on normal runs.

The passengers are berthed in cabins on the upper and bridge decks. Normally there is accommodation for 88 first and 41 second class passengers, but as is usual with the British India Steam Navigation Company's vessels of this class, some of the cabins can be altered so that the number of first class passengers carried may be increased or diminished as required. They are mainly two and three berth cabins, all arranged with direct access to the side of the hull, so as afford natural lighting in each room. At the forward end of the upper deck is the dining saloon with a large number of small tables, and at the after end is the second class dining saloon. Forward of the promenade deck is a first class music room and a separate smoking room, while aft is the second class smoking room. Officers and engineers are both berthed on the boat deck, the latter being at the after end. This system of having the engineers and officers on the same deck was one of the innovations of the British India Steam Navigation Company, some years ago, and is now very popular.

MAIN PROPELLING MACHINERY

For propulsion, two four-cycle Diesel engines are installed. These are of the eight cylinder type constructed by the North British Diesel Engine Works and are of their own design, developed after the war. Each engine is rated at 2,330 indicated horsepower at 96 revolutions per minute and this is roughly equivalent to 2,000 steam indicated horsepower. There is little that is novel in the construction of these engines, which drive their own high pressure three-stage air compressors, but no other auxiliaries. Although separate piston cooling and jacket cooling pumps are provided, sea water is used for both purposes, the pressure in the case of the piston cooling circuit being of course higher than that used for cooling the cylinders.

As the *Dumana* is liable to enter rivers which are extremely muddy and there is a possibility of a considerable amount of deposit being drawn through the circulating system, arrangements are made whereby the piston cooling pumps draw the sea water through a special tank provided with filters. The main reason why some Diesel engine manufacturers (as, for instance, Harland & Wolff) employ fresh water cooling for the pistons is because of this danger of muddy water and not on account of the possibility of salt being deposited in the cooling spaces in the pistons as is sometimes imagined.

The arrangement of the auxiliary machinery in a motorship affords an interesting study, since each individual

builder seems to have a different idea of the needs of the case from that of other manufacturers. As previously mentioned, electricity is used for practically all purposes on the *Dumana* and the supply is derived from two generating sets, each of 215 kilowatts and driven by a six cylinder engine running at about 375 revolutions per minute—a rather high speed for marine work. The voltage of supply is 220, as usual, and this is used both for lighting and power, whereas on most Scandinavian motorships, a rotary converter is installed reducing the pressure to 110 volts for lighting.

Most British builders are in favor of having a high powered maneuvering air compressing plant, and the *Dumana* affords an excellent example of this tendency. There are two auxiliary three-stage air compressors; one is coupled to an electric motor developing 250 brake horsepower, while the other is driven by a six cylinder Diesel engine of the same power as that coupled to the two electric generators, namely 300 brake horsepower. The total power for driving these auxiliary compressors is therefore no less than 550 brake horsepower which certainly seems somewhat heavy on a vessel where the propelling plant develops well under 4,000 brake horsepower.

On the trials, a speed of approximately $13\frac{1}{2}$ knots was attained.

Single Cylinder, Double Acting, Four Cycle 1000-Brake Horsepower Experimental Diesel Engine Built by Burmeister and Wain and Operated for Four Months in Their Experimental Shop at Christianshavn

Study Insurance Problems to Prevent Losses

By "Bordereaux"

Marine insurance is one of the greatest economic factors in the shipping industry. Without it ocean commerce could hardly exist. It is a guaranty against loss from legitimate sea perils, many of which are unpreventable. Pilferage, unseaworthiness, overloading and nefarious practices, however, can be reduced to a minimum not only lowering the cost of insurance but in many cases preventing total losses; for the courts do not always decide against the underwriters.

RESPONSIBILITY of carries for pilferage losses is pressing again to the fore. There seems to be something of a revival in this class of depredations. Merchants are complaining of rifled cases in practically every trade route, and especially as regards Mexico and South America. The Mexican situation is particularly bad. Investigations by underwriters have uncovered a serious condition at Vera Cruz and other ports in Mexico, everything pointing to a systematic conspiracy on the part of customs authorities at Vera Cruz and unscrupulous merchants at Mexico City to rob merchandise while in transit through the customs.

Chile has produced the latest device designed to curb theft and pilferage, the plan being to place on ship captains the responsibility for missing or underweight packages. United States Consul George A. Makins, at Valparaiso, refers to it in his recent reports. He says: "The Chilean customs ordinance (Art. 89, Paragraph 3) provides that a fine may be imposed on the captain of the vessel where cases are found to have been opened or their contents removed without the written permission of the customs authorities. In a recent case at Valparaiso, where it was found that 460 parcels of cargo had had their contents stolen before being discharged, a fine of 5 pesos per package was imposed on the captain of the vessel. The steamship company moved for dismissal, arguing that this was a distortion of the intent of the law. The decision was contested and brought before the Chilean Supreme Court, which upheld the original decision and ordered the captain of the vessel to pay the fine."

Importance of Dunnage

ACCORDING to a recent decision of the United States District Court, S. D., New York, 285 Fed. Rep., 612, under the Harter Act ship owners are under obligation to furnish seaworthy vessels, and grain-carrying ships must be properly dunnaged to protect cargo from water damage. This was a suit in admiralty brought by the Midland Linseed Products Company against the schooner *Oakley C. Curtis* and the France and Canada Steamship Corporation, on a libel to recover \$146,000 damages to a cargo of linseed transported from Buenos Aires to New York. The court ruled against an extension of the Harter Act as contended by the respondents to the effect that they warranted the seaworthiness of the vessel in so far only as ordinary care can provide and that the vessel was relieved only from liability arising from an act of God, perils of the sea, etc. It was shown that the hull was entirely seaworthy but that the trouble lay with the dunnage, which was improper and insufficient.

In the matter of dunnage it was proven that the pieces of boards used for sealing the sides of the vessel had no protecting sidepieces, as they should have had, and that the boards were spaced too far apart, with the result that many linseed bags pressed or pushed into the spaces and against the ceiling or skin of the ship. The consequence was that the bags and their contents in the lower hold were wetted during the heavy seas that prevailed. Furthermore, air strakes and spaces between the beams extending into the bilges were not securely covered, as they should have been, and loose grain

was, on that account, enabled to sift to the bilge between the timbers of the vessel, clogging the pumps and preventing the pumping out of the hold. As to water coming in at the sides, the respondents were deemed liable for damage from this source, since it was shown that if the 'tween-deck and the lower hold had been properly sealed or dunnaged the water would have passed into the bilges and would have been pumped out.

Lightning a Sea Peril

A WEEK or so ago the steamer *Albania* arrived in New York with word of having narrowly escaped being struck by lightning while in mid-ocean, and the consequence has been a revival of the perennial question "Is Lightning a Sea Peril?" Oddly enough, there appears to be doubt in many quarters as to the propriety of including lightning among perils of the sea, the argument being that lightning is no more such a peril than rain and that there is nothing of an extraordinary character to it and that it is in no wise peculiar to the sea. In this connection it is interesting to recall the views of the Supreme Court of South Carolina, in the recent case of the Clinchfield Fuel Company vs. the Aetna Insurance Company, as regards the meaning of perils of the sea.

This was an action brought by the fuel company against the insurers to recover for the loss of a cargo of coal shipped per steamer *Northwestern* from Charleston, S. C., to Cuba. The vessel was of wood, built in 1881 and twice rebuilt. On the passage she encountered heavy winds and cross seas, and on the third day out she was beached in order, if possible, to save the crew and cargo. She soon broke up, however, and with the cargo was a total loss. In the course of his opinion the presiding judge observed of the term "perils of the sea" that it is a phrase interpreted with great strictness in connection with bills of lading but with surprising elasticity where the assured is claiming a recovery under a policy of insurance. Such a variance of interpretation the judge admitted to be erroneous, but he held that in any event the term must be interpreted with considerable elasticity when applied to policies of insurance. The court cited authorities to show that even though a storm was not so extraordinary as to have resulted from uncommon causes yet it was unnecessary to show such a storm in order to have a claim under the perils of the sea clause in a marine insurance policy. Thus Carver, in "Carriage by Sea," says: "Upon this it must be remarked that losses need not be extraordinary, in the sense of arising from causes which are uncommon. Rough seas, which are characteristically sea perils, are common incidents of a voyage." The court quoted from the case of *The Hazard vs. Peters*, wherein it was held that "they (the underwriters) insure against losses from extraordinary occurrences only, such as stress of weather, winds and waves, lightning, tempests, rocks, etc."

While on the question of "perils of the sea" it may be well to recall the admirable working definition of this mooted phrase as given in the decision of Judge Hough, Circuit Court of Appeals, in the *Rosalie* case; 264 Fed. Rep. 285.

He therein stated that "a peril of the seas which forms a good exception in a bill of lading means something so catastrophic as to triumph over those safeguards by which skillful and vigilant seamen usually bring ship and cargo to port in safety."

Barge Canal Outlook

UNDERWRITERS and shipowners are finding much to interest them in the current news of activity as respects business on the New York State Barge Canal during the present season. All indications point to an extended use of the canal by shippers in the Middle Western States. According to Superintendent of Public Works Walsh, financial interests at Cleveland, Detroit and Duluth have under consideration a considerable investment in equipment to be used on that waterway and on the Great Lakes. Contracts have already been let by one group for two Diesel-engined, electrically-driven motor ships, each capable of carrying two thousand tons of freight on the canal draft, and it is expected that they will be ready for use by midsummer. Crude rubber importations will probably be carried by the canal to Cleveland and thence by rail to Akron, at a saving of \$2 per ton over the all-rail rate, provided adequate terminal facilities can be effected at Cleveland. Import flaxseed for Cleveland and Toledo will probably be resumed by way of the canal, running into hundreds of thousands of tons. Holland building brick is another commodity that will probably be moved to the Western market from New York via the canal.

Transshipment Problem

THE collapse of the Three Star Line has brought an embarrassing situation upon the underwriters, especially as regards the problem of a transshipment of cargoes now tied up at various points. Three of the company's steamers are now detained at widely separated ports—the *Bacchus* at Marseilles, the *Phoebus* at Philadelphia, and the *Janus* at Oran, Algiers. Urgent questions have developed in connection with the insurance carried on their cargoes, and responsibility for getting the merchandise forward to destination. On account of the financial condition of the line these cargoes have been discharged and await the further instructions of the shippers who own them. Such a situation naturally entails enormous expense upon the shippers, the freight having been prepaid and the merchandise lying scattered at remote points. No sea peril is involved and claims on that account are not entertained. Responsibility for transshipment, under ordinary circumstances, would devolve upon the carrier, but in the conditions of the present case it will have to rest with the owners of the cargoes. As regards the validity of the insurance, the majority of the underwriters concerned are maintaining that an abandonment of voyage has occurred, and that extended coverage must be applied for by the insured and secured by the payment of additional premium.

Overloading

IT is universally admitted that overloading constitutes a factor of decided danger to ship and cargo. Recent instances of it have been occasioning underwriters considerable anxiety; to such an extent, indeed, as to arouse consideration of the introduction of a clause in policies under the terms of which the policy must be warranted free of any claim incurred during a voyage on which the vessel sailed in an overloaded condition. This has been directly the outcome of repeated warnings to the effect that foreign steamers have been sailing regularly from the River Plate

with cargoes of grain loaded to a depth that submerges their load lines at least by a foot. There is nothing in the hull policy, unfortunately, to prevent an owner from overloading his vessel. In the event of a loss in consequence, the underwriter is forced to pay the bill. It will be generally admitted that something ought to be done, by underwriters if others will not take the lead, to put an end to a practice that is the outgrowth of greed and which imperils the lives of the crew and jeopardizes ship and cargo.

Marine Motor for Small Boat Propulsion

A SMALL size, low price motor, having a special feature of interchangeable parts standard to Ford motors, is being built on a quantity basis by a recently organized corporation of Detroit, the Du Brie Marine Motors. This motor is a single cylinder four-cycle 5 horsepower type weighing 100 pounds. It is

Du Brie Marine Motor

equipped with a Bosch high tension magneto, an impulse starter, a Holley carburetor and propeller wheel. This motor is also equipped for twin-screw installation with either right or left hand rotation. Forty-four of the parts of the Du Brie marine motor are interchangeable with the standard parts of the Ford automobile engines, thus making possible replacements at a minimum cost.

It is claimed that this motor is very flexible, due to the hot spot manifold and a special type camshaft. It has been demonstrated that the motor may be slowed down to 180 revolutions per minute and run at this speed indefinitely. Arrangements have been made with Chris Smith and Sons Boat Company of Algonac, Mich., builders of racing craft, to furnish plans and specifications for a 25-foot boat specially designed for use with this motor. These plans are furnished with each motor upon request.

Liability of Vessels Sold by Government

IN the case of the *Texas Company vs. United States*, 285 Federal Reporter, 643, a libel was filed against the *M. Morgan*, previously known as the *Retriever*, to recover damages for a negligent collision. At the time the cause of action arose the vessel was owned by the United States but was subsequently sold. The Court held, that the provisions of the Suits in Admiralty Act of March 9, 1920, section 5, which states that suits thereunder on causes of action arising prior to its taking effect must be brought within one year after it went into effect, does not apply to a suit in rem authorized by the Act of September 7, 1916, (Comp. Stat. sec. 8146a, etc.) against a vessel which has been sold by the government, and for which the United States assumes liability under sec. 4 of the Suits in Admiralty Act.

The Spring meeting of the American Society of Mechanical Engineers will be held in Montreal, Canada, May 28 to 31. The Engineering Institute of Canada will attend the meeting.

Current Admiralty Decisions of Special Interest

By Calvert B. Gill*

Maritime Contract With City Binding

A MARITIME contract with a city for the unloading of a sunken scow, says the Court in *Rodgers & Hagerty, Inc., vs. City of New York*, 285 Federal Reporter, can be enforced in a court of Admiralty without regard to provisions of the city charter limiting its liability on contracts, since the enforcement of those provisions of charter in a court of Admiralty would destroy the unity of the Admiralty jurisdiction that is preserved by constitution of the United States.

Damages Occurring on Dock Outside of Admiralty Jurisdiction

THE seeking to recover damages arising from a tort which occurred on a dock at which a vessel is moored, as the plaintiff endeavored to do in the case of *Spitzer & Annette Rolph*, 285 Federal Reporter, 446, the Court is without the pale of Admiralty cognizance so that exclusive jurisdiction of Admiralty is not invaded by bringing such action in a State court, and the cause is not able to a Federal court on that ground. A vessel is "citizen within the purview of the statutes authorizing removal of causes to the Federal courts, so that a cause tried in the State court by a citizen of the State against a vessel, whose home port was in another State cannot be removed on the ground of diversity of citizenship.

Enforcement of Maritime Liens Where Common Ownership Exists

THE fact that the corporation furnishing supplies to a vessel and the corporation owning the vessel had largely the same stockholders and many of the officers were identical does not make the supply corporation the owner of the vessel, nor indicate the supplies were furnished on the credit of the owning corporation, if the officers of the two corporations, by whom the supplies were sold and purchased, were different and there is no showing that the supply corporation had used its power to compel the vessel to purchase supplies from

A maritime lien is denied to a party, who would otherwise be entitled to it because of his relation to the vessel, when he is either a real part owner of the vessel, occupying a fiduciary relation toward her and her owners or deals with her on her account; that is, the lien is denied because of insuperable legal difficulties in the enforcement of the lien, because to recognize it would be inequitable to the other claimants, says the Court in the case of *the Gloucester*, 285 Federal Reporter, 579.

Obligation of Owner to Provide Dunnage

THE *Oakley C. Curtis*, 285 Federal Reporter, 612, is a case where the owner was held liable to recover damages to a cargo of grain damaged by sea water while in transit. The Court said: "It is established that a vessel beginning her voyage in a time charter party at Law, Baltimore, Md.

of year when storms at sea are prevalent, carrying grain, must install dunnage, so as to keep the cargo free from water which may reasonably be expected to enter during the voyage from strains and stress of weather or other leakage." The Harter Act, Sec. 3, does not exempt the owner of a chartered vessel from the obligation to furnish a vessel which is seaworthy and fit for the cargo to be carried at the commencement of the voyage.

Offer of Re-instatement Annuls Wrongful Discharge

A PROMPT offer of reinstatement operates to annul a hasty and wrongful discharge of a seaman, and in such case no penalty of one month's wages under Revised Statutes, Sec. 4527, is due the seaman says the Court in *The Meton*, 4 American Maritime Cases, 296, where the plaintiff was discharged after four days of employment, but was offered reinstatement the same day he was discharged, which he refused.

Recovery for Supplies Furnished

A MARITIME lien, under the act of June 23, 1910, sections 1-3," says the Court in the case of *El Amigo*, 285 Federal Reporter, 868, in which the plaintiff endeavored to recover for supplies furnished to a ship while under a charter party but was held out as being owned by the parties ordering the supplies, for supplies furnished a foreign vessel "is not defeated by showing that such person was charterer, without authority to bind the vessel, where those furnishing the supplies had no knowledge or means of knowledge of such facts." That the charging of the necessities against the person ordering them does not affect the furnisher's right to a lien where the necessities are furnished under circumstances giving rise to a lien.

Breach of Charter Party

IN the case of *Galban Lobo & Company vs. United States*, 285 Federal Reporter, 665, wherein the plaintiff brought suit in Admiralty in personam for damages flowing out of a breach of a charter party. The plaintiff being a Cuban corporation without a residence or principal place of business in this country, the Court held that a suit against the United States cannot be maintained under the Suits in Admiralty Act of March 9th, 1920, section 2, by a non-resident having no place of business in the United States, where the cause of action alleged would not support a suit in rem. The clause in the statute permitting suit to be brought in the district in which the vessel "charged with liability is found" is also unavailing, as there could be no liability in rem where the cargo was never placed on board the vessel, and the charter was cancelled because the vessel was not in readiness to receive it. "Charged with liability" does not mean "attachable by foreign process" but charged with a maritime lien. Nor is the cancellation of a charter party by the charterer, because of failure to have the vessel ready to receive cargo, an abandonment of a claim for damages arising from expenditures for lighterage made necessary by the breach of contract.

Questions and Answers Relating to Naval Architecture and Marine Engineering

Conducted by James L. Bates, Naval Architect, and W. B. Newton, Marine Engineer

This department is maintained for the purpose of answering all questions relating to ships and their machinery. All inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

Hot Well Salinity Indicator

Q. (1194).—Please advise if harmful electro action would be likely to occur under the following conditions: A 110-volt light circuit is so arranged that in case sea water should find its way into the hot well the salt water would complete circuit and cause a light to show. If the hot well were absolutely fresh, enough current could not pass between the terminals to cause the light to glow.—D. S. R.

A. (1194).—If the action of the light circuit was sufficiently positive and certain to indicate satisfactorily and promptly small degrees of salinity or acidity, it should be possible to relieve the conditions responsible before serious damage could be done by electrolytic action.

Why Naval Vessels Have a Clipper Stem

Q. (1197).—What is the reason for the different practice in the United States Navy as to type of stem as compared with that in the merchant service?

A. (1197).—The clipper or overhanging stem as fitted on naval vessels provides:

- (a) Satisfactory stowage for stockless anchors.
- (b) A topside shape which greatly assists in bringing the anchor snugly to its stowage position.
- (c) A location of hawse hole such that the anchor drops well clear of the fore foot.
- (d) A lead of anchor chain (particularly in the case of the center anchor) such that the danger of nipping across the stem is minimized.
- (e) A natural ending, without extreme snubbing, to the vessel's topside waterlines in spite of the rather excessive flare generally used.

In the merchant service the vessels do not spend the time at anchor that the naval vessel does. Speeds are lower and freeboards are greater so that the stowage of an anchor well clear of the ordinary seas is not so difficult. The shape of the sections below the waterline does not require the hawse hole to be so far from the centerline of the ship.

Which Methods Are Preferable for Calculating Displacement, Stability, etc.?

Q. (1195).—Do you consider the method for calculating displacement, stability, etc., used by the Navy Department superior to the methods which are based upon the use of the integrator?

A. (1195).—The method in use by the Navy Department is based upon the use of the trapezoidal rule for integration. This rule simplifies the numerical work but necessitates compensation for the effect of curvature when the ordinates are measured either from the cross sections for immersed area or from the curve of sectional areas for displacement.

When using the integrator the areas are obtained by the

instrument and generally "put through" Simpson's rule or some other similar rule with which the compensation necessary with the trapezoidal rule is not required.

The degree of accuracy to be expected is about the same with either method except that all figures used in the Navy Department method are entered on regular forms and are therefore, readily subject to check. Moreover, in case any question of the accuracy of the work or of the exact step taken arises, the calculations made by the department's method are invaluable for ready reference. This is not true to the same extent of the integrator methods. In the writer's experience, particularly in large organizations, in which the personnel making routine calculations are subject to considerable change, methods which can easily be reduced to definite forms and which, when carried out properly, result in accurate records of the work done are of especial value.

If the data desired are for one draft only, time will probably be saved by using the integrator. If a complete displacement sheet or cross curves of stability for a considerable range of displacement are required, the department's method would probably be shorter.

Relative Efficiency of Methods for Estimating Weights

Q. (1196).—What can you say of the relative efficiency of the several methods commonly used in making preliminary weight estimates?

A. (1196).—This is too broad a subject to be covered in this department. The following notes may be helpful in outlining it for your further investigation:

Let it first be agreed that the discussion applies only to estimates for hull proper as it is comparatively simple to make weight allowances for machinery, outfit, equipment, etc. The hull, moreover, forms a very large proportion of the weight of the ordinary merchant ship. Hence the hull weight is the principal object of the preliminary weight estimates.

These are five methods of arriving at a figure for hull weight which are generally used.

(a) Weight per linear foot of midship section multiplied by length times a constant = hull weight. The weight per foot is estimated for the ship in hand and the constant is taken from experience with other ships of the type.

(b) Length times beam times depth times a constant = hull weight. The constant is in this case also taken from other ships of the type.

(c) Recording of the weights of the hull groups such as framing, bulkheads, shell plating, etc., as curves plotted as cubic number $(L \times B \times D)$ or the numeral of a classification society. Then building up a hull weight by taking group weights off from these curves.

(d) When the group weights of a similar ship are available taking them as a basis from which to proportion weights for the new ship in the ratio of dimensions, and etc., allowances being for difference in scantlings.

(e) Lay out the principal structural members, as deck, shell, etc., to a small scale and estimate weights on an "allowance for unit area" basis.

Of course in all the above methods care must be taken to make proper allowance for special features, perhaps not covered in the type used.

The writer has used all of the above methods except (c) and found them all reasonably satisfactory, if carefully and understandingly used. It would seem that (c) would be very satisfactory when dealing with well established types for which a considerable quantity of information was available.

The writer has found (d) to be the best where a really satisfactory type ship and its data are available. When investigating a new field (e) is the best.

Methods (a) and (b) do not give as accurate results as (d) and (e) unless the data upon which they are based are exceptionally good. Methods (a) and (b) give no assistance in fixing the location of the center of gravity of the hull. Methods (c), (d) and (e) are satisfactory in this respect.

NEW BOOKS

SHIP SUBSIDIES. (Reference Shelf Series.) Compiled by Lamar T. Berman. Size, 5 by 7 $\frac{3}{4}$ inches. Pages, 112. New York, 1923: The H. T. Wilson Company.

This volume is written along the general lines of the Reference Shelf Series. The history and present status of the subsidy question and articles covering arguments for and against are included.

A feature of the book is an outline of affirmative and negative briefs suitable for a debate which should be of particular interest to schools and debating societies. The bibliography giving a long list of references to books and periodicals in which the subsidy question is discussed is also of value.

Industrial Oil Engineering

Reviewed by James A. Kelley*

HANDBOOK OF INDUSTRIAL OIL ENGINEERING. By John Rome Battle. Size, 5 $\frac{1}{2}$ by 7 $\frac{3}{4}$ inches. Pages, 1,131. Illustrations, 471. Philadelphia, 1923: J. B. Lippincott Company.

This volume is essentially a handbook on the diversified uses of oil and its scope includes, as set forth on the title page, "A Reference Book of Data, relating to lubrication and industrial oils, including tables, general oil information, engineering and industrial requirements for the use of oil engineers, oil salesmen, oil equipment manufacturers, mechanical engineers, machinery designers, mill and power plant superintendents, and others interested in the efficient utilization of oil products and equipment and the conservation of power. It includes the Lubricating Engineer's Handbook revised."

At the outset it should be stated that this work does not include data or text concerning oil burning equipment and the burning of oil. The author announces his intention of publishing a manuscript especially covering this important branch of oil engineering.

The volume is replete with data, tables, diagrams and illustrations, and covers each subject in a remarkably clear and thorough manner. For example, the author is not content with describing the lubrication of bearings but gives a great deal of valuable information about every type of bearing encountered in practice. Again, in treating the subject of lubricating forming machinery, cutting metal, etc., a great deal of instructive data is included concerning the theory of cutting operations.

A recounting of the treatment of each phase of the industry involved in core making, textile mills, etc., etc., would be too

*Naval architect, Morse Dry Dock and Repair Company, Brooklyn, N. Y.

lengthy for this review, but it is to be remarked that in each case, the subject is thoroughly treated, and every chapter speaks loudly of the author's exhaustive and painstaking research and study. It is only to be regretted that the inclusion of the oil burning field would have made this splendid volume too lengthy.

LETTERS TO THE EDITOR

Automatic Steering

It was with a great deal of interest that I read in your March issue the article by Mr. R. H. Rogers, describing the "Wake System of Automatic Steering." It certainly appears to be a simple method and to possess a considerable degree of merit, in a great measure overcoming the difficulty of personal judgment as to the leeway the ship is making.

It does that, however, only in a measure. It takes care of leeway produced by the action of the wind, or through the behavior of the ship as to its steering, but it introduces a new error, which in many cases may lead to shipwreck, if too much reliance is placed on the automatic correctness of the steering.

This is due to the fact that when crossing a water current, whether tidal or of other kind, the drag used will drift with the current and thus make the wire connecting it to the vessel form an angle with the true course made good by the vessel. This angle will depend upon the speed of the water current and the angle at which the ship crosses the same.

A little calculation will show that with currents such as are frequently found along coasts, and with ordinary speeds of ships, this introduces a very serious error, which, especially in a fog, might easily lead to disaster. If this "wake system" is used, it is therefore just as important for the navigator to exercise his personal judgment as with any other kind of steering, automatic or otherwise, and it is therefore dangerous to spread the idea that any new system such as now introduced will overcome vigil on the part of the officers of the ship.

It is true that Mr. Rogers states that cumulative errors may occur, but that is something quite different from mentioning this, in reality, very serious error that is caused through the very principle under which the apparatus operates. At any rate it would seem important enough to have attention called to it.

Los Angeles, Cal.

E. T. SEDERHOLM.

Fletcher Company Wins St. Louis Case

Suit Attracted Considerable Attention, There Being More Money Involved Than in Any Other Pending Admiralty Case

THE case of International Mercantile Marine Company against W. & A. Fletcher Company, arising out of the burning of the former American liner *St. Louis*, at the shipyard of W. & A. Fletcher Company, in Hoboken, on January 8, 1920, has been decided in favor of the W. & A. Fletcher Company by United States Circuit Judge Ward, sitting in admiralty in the United States District Court for the Southern District of New York.

The case has attracted a great deal of attention in shipping and shipbuilding circles because of the large amount of money involved, probably the largest in any admiralty case pending in the courts. While the suit was brought in the name of the International Mercantile Marine Company, the real parties in interest were underwriters, particularly British underwriters, who, the court said, properly should have been made

parties to the suit. The International Mercantile Marine Company was not itself interested in the litigation in any way.

SOUGHT TO RECOVER \$2,000,000

The underwriters had paid a total loss on the *St. Louis* of approximately \$1,600,000, and they sought to recover \$2,000,000 from the Fletcher Company, not only for the total loss of the *St. Louis*, but also for damages to the *Kroonland*, undergoing repairs at the Fletcher yard, which resulted from the *St. Louis* listing over on her while the fire was being extinguished.

The suit was brought upon the charge that the fire had been started by the negligent use of a blow torch and a volatile varnish remover, in removing varnish from the grand staircase of the vessel. The court held that the fire was not started by the use of a blow torch; that a torch was not used where libellant's witnesses had claimed, but it found that the fire was started in a piece of waste.

CONTRACT MADE INSURANCE COMPANIES RESPONSIBLE

The court also found that it was a condition of the agreement under which the work was undertaken that the Fletcher Company should not be liable for losses ordinarily coverable by marine insurance, of which fire was one. Subsequent to the time the agreement was made, the International Mercantile Marine Company, as agent of the United States Shipping Board, negotiated with the Fletcher Company and Cramp Shipbuilding Company for the repair of the *Leviathan*, and in the offer which was submitted by the Fletcher and Cramp companies there was inserted a provision that the United States would assume all usual risks on the steamer and materials delivered to the contractor, ordinarily coverable by insurance, and the court held that the offer to repair the *Leviathan* evidenced the contract covering the repair of the *St. Louis*, as the Fletcher and Cramp companies had offered to make the repairs on the *Leviathan* on the same terms and conditions as the Fletcher Company was making them on the International Mercantile Marine Company's own ships.

Messrs. Ira A. Campbell and John M. Woolsey, of the firm of Kirlin, Woolsey, Campbell, Hickox & Keating, and Clarence Bishop Smith, of the firm of Haight, Smith, Griffin & Deming, appeared for W. & A. Fletcher Company, and Messrs. Charles C. Burlingham and Chauncey I. Clark, of the firm of Burlingham, Veeder, Masten & Fearey, and Earle Farwell, of the firm of Barry, Wainwright, Thatcher & Symmers, appeared for the underwriters.

PERSONAL MENTION

BEN BARBER, for three years district counsel for the north-eastern district of the United States Shipping Board, has resigned to enter private practice in New York.

N. M. LEACH was elected president of the Steele Steamship Line at the recent annual meeting of the directors, held at New Orleans. Semmes Steele was elected vice-president.

J. V. BLAKE, assistant to W. A. Morrissey, tank steamship executive for the United States Shipping Board, has resigned to become manager of tank steamships for the Pure Oil Company.

THOMAS G. PLANT, formerly manager for McCormick, McPherson and Lapham, has been appointed operating manager of the American-Hawaiian Line, San Francisco, Cal. Mr. Plant was at one time the United States Shipping Board's assistant director at San Francisco.

C. C. JACOBSON, vice-president of the National Association of Marine Designers and formerly in the marine division of the Department of Plant & Structures of the City of New York, is now connected with the engineering department of the Atlantic, Gulf & Pacific Company, engineers and contractors, 2407 Park Row Building, New York City.

R. T. GORDON, for the past eight years connected with the New York sales office of the Alberger Pump and Condenser Company, has resigned to accept a position in the sales department of Dean Brothers Company, of Indianapolis, Ind., manufacturers of pumping machinery, and will be located in their New York office at 141 Broadway.

CAPTAIN THOMAS KIER has been appointed to the command of the new Hamburg-American Line steamship *Albert Ballin*, according to information received from Hamburg by the United American Lines who are the United States agents for the Hamburg-American Line. Captain Kier, who is commodore of the Hamburg-American fleet, has been in service with the company for thirty years. Prior to the war he was commander of the *Imperator*.

CAPTAIN JOHN BRADSHAW, commander of the new 27,000-ton Red Star Liner *Belgenland*, which recently arrived at New York on her maiden voyage from Antwerp, is an American citizen and a resident

Captain John Bradshaw

of New York City. His first command was that of the *Rhyndland*, of the Red Star Line, to which he was appointed in 1899. Since that date he has held command of the *Samland*, *Finland*, *Kroonland* and *Lapland*, the last-named from her debut in 1912 until his appointment to the new *Belgenland* in January of the present year. In command of the *Lapland* during the World War, Captain Bradshaw made seventy-four of the seventy-six voyages of that vessel as a troop transport. Captain Bradshaw had the distinction of commanding one of the first steamers to take troops from Canada to England for the conflict, as the *Lapland* was in the first convoy that put out from Montreal. She was also the first ship to bring Canadian troops home after the signing of the armistice.

E. P. ERCKENBRACK, who has been filling the position of district director of the United States Shipping Board for Brazil at Rio since February 1, 1920, has been appointed district director of the Board at Seattle, succeeding Robert M. Semmes, resigned. Mr. Erckenbrack is very well known on the Pacific Coast and undoubtedly his appointment to the office will result in increased business for Board line vessels trading to and from the Puget Sound district.

F. W. LEAHY, president of the Leahy Engineering Company, Cincinnati, O., has been appointed supervising engineer of The Campbell's Creek Coal Company. In this capacity he will have charge of both the new construction and the maintenance of all floating equipment of this company. He will also continue as president of the Leahy Engineering Company. Mr. Leahy has had many years' experience as chief engineer of ocean-going ships and is well known on both the Atlantic and Pacific coasts. Before establishing the Leahy Engineering Company he was for several years New York manager of the Diamond Power Specialty Company.

HUGH GALLAGHER, veteran of the Admiral line, has been promoted from superintendent of the company to assistant operating manager.

CAPTAIN R. C. BRENNAN, for a number of years port captain of the Admiral line, has been appointed operating manager of the company and will have charge of all physical operations of the company's extensive coastwise services.

G. H. FROEBEL, the new manager of the marine sales department of the Westinghouse Electric & Manufacturing Company, whose appointment, effective April 1, was announced in our April issue, will have his headquarters at the East Pittsburgh works of the Westinghouse Company.

G. H. Froebel

In his new position, he will be a member of the Domestic Sales Committee, composed of the heads of the various sales departments. Mr. Froebel was born at Boerne, Tex., on October 1, 1889, and was graduated from the San Antonio High School in 1907 and attended the University of Texas from 1907 to 1909. The new marine head entered the employ of the Westing-

house Company in November, 1912, taking up the company's graduate apprentice shop course. He was transferred in 1914 to the Dallas, Texas, office of the company as industrial salesman. Two years later he opened the Houston, Tex., branch office as manager of the Industrial Division for the entire district. He remained there until 1918, when he entered the United States Army, as a lieutenant in the Construction Division. After being discharged from the Army in April, 1919, he re-entered the employ of the Westinghouse Company and was placed in charge of the Houston branch office, of which he became manager in November, 1919. Mr. Froebel is a member of the American Society of Military Engineers and an associate member of the American Institute of Electrical Engineers.

WILLIAM M. KENNEDY, until recently associated with the United States Shipping Board at 45 Broadway, New York, as supervising local manager, has assumed in full the duties of assistant to Andrew Fletcher, Jr., in the direction of work at the shipyard of W. & A. Fletcher, Hoboken, N. J. Mr. Kennedy resigned from the Shipping Board to undertake the supervision of work at the Fletcher plant several weeks ago and he brings to his new connection a wealth of experience gained in more than twenty-two years' association with ships and ship construction. Starting as an apprentice with the Maryland Steel Company, Sparrow's Point, Md., he subsequently became a mechanic, supervisor of new construction, draftsman, estimator and executive in charge of estimating and planning. During this time he was employed on work at several private shipyards, including the Maryland Steel Company and the Fore River Shipbuilding Company at Quincy, Mass., as well as naval construction at the Charleston, S. C., and New York Navy Yards. In 1915 Mr. Kennedy became associated with work at the Panama Canal in an executive capacity and played a prominent part in the installation of the planning and production system used in the canal dry docks and shops. He subsequently left the Panama Canal to become assistant production manager of the Merchant Shipbuilding Corporation at Harriman, Pa., later becoming assistant works manager and then assistant

to the general manager. On April 1, 1920, he was transferred to the Chester yard of the Merchant Shipbuilding Corporation as works superintendent and about a year later resigned and became associated with the Shipping Board.

OBITUARY

GEORGE PALMER FENNER, assistant treasurer of the American-Hawaiian Steamship Company, died at his home in Flushing, L. I., recently. He was born in Brighton, England, and had engaged in the steamship business the greater part of his life.

WILLIAM W. STODDARD, the oldest employee of the New York Navy Yard, died at his home in Brooklyn, N. Y., on April 3 at the age of 87. Mr. Stoddard was a veteran of the civil war. In the Spanish war he helped to outfit naval vessels for service, and again in the world war he performed similar duty, having charge of 6,000 men at the New York Navy Yard.

ADDISON CHILDS DAMON, associated with the yacht building concern of George Lawley & Son Corporation in Neponset, Mass., died recently at his home, in Dorchester, Mass. Mr. Damon was sixty-two years old. Almost immediately upon leaving school he associated himself with the Lawley corporation, where he became an expert draughtsman and at the time of his death had been in its employ forty years.

CAPTAIN GEORGE L. NORTON, from 1885 to 1919 editor and publisher of *The Marine Journal*, died at his home in New York on March 24, at the age of 87. Captain Norton

Capt. George L. Norton

was born in Castine, Me., in 1837 and at the age of 14 went to sea. Starting at the bottom, this sturdy scion of a New England sea-faring family rapidly rose to a position of command and influence in the coastwise steamship service. At the outbreak of the civil war he was second officer of the steamship *Saxon*, which became an army transport. Later he became first officer and master of the *Saxon* and in 1866 took command of the *Ashland*, pioneer steamship of the Metropolitan Steamship Line running on the outside route between New York and Boston. In 1871 Captain Norton assumed command of the *Crescent City*, operating in the New York-New Orleans passenger and cargo service and in the same year he was appointed harbor master at the Port of New Orleans. Five years later Captain Norton received the appointment as supervising inspector of steam vessels for the Gulf States, a post which he held for eight years. In 1885 he came to New York and started his long and eminently successful journalistic career as editor and publisher of *The Marine Journal*. In that year he became a member of the National Board of Steam Navigation and of the Marine Society of the City of New York. His long life brought to Captain Norton many honors and a host of friends among men prominent in shipping and government circles. He was a member of the Board of Pilot Commissioners and for several years a trustee of Sailors' Snug Harbor.

The Month's Shipping and Shipbuilding News in Brief

Shipyard, Steamship and Port Activities and Other Notes
of Interest in All Branches of the Marine Industries

First Quarter Produces Ninety Million Dollar Business

OVER ninety million dollars' worth of marine work, all classes, has been reported in MARINE ENGINEERING AND SHIPPING AGE from January 1 to April 1 of this year, according to statistics compiled from our records. These figures include ship and port work, both contemplated and awarded.

Bearing in mind the general business situation at home and abroad, it is conceded that the first quarter of the year in maritime affairs presents a highly credible showing. The figures given represent only that work which the magazine reported and only those contract awards have been considered for which definite prices were available.

Vessel construction and reconditioning recorded in these columns during the first three months of the year as under contemplation totaled \$12,005,000, while contracts were awarded for similar work in the amount of \$8,100,267. A strong trend in the direction of port improvement is seen in the total of \$61,614,696 reported in the "contemplated" stage in this branch of marine work, with \$8,486,071 in contracts placed. The total for ship work, contemplated and awarded, is \$20,105,276, and that for port developments \$70,100,767, bringing the grand total for all classes up to \$90,206,034.

Optimism is the key word for the marine field at the present time and the only basis upon which constructive progress can continue. It is realized that America's maritime industry must carry on in spite of the non-passage of the Subsidy Bill, and indications are that the second quarter of the year will be even more productive of substantial business than the first quarter. Ship construction and reconditioning contracts which will necessitate the expenditure of many millions of dollars are now pending, a goodly portion of which will have arrived at the "awarded" stage in the near future.

With these facts to consider, there seems to be every reason why every business man having an active interest in the marine industry should put forth renewed effort to see that his company gets its share of the contracts being placed every week.

Specifications Out for Ferryboat for New York Central

PLANS and specifications for the construction of a steel ferryboat for the New York Central Railroad Company have been issued, bids to be opened on May 15. J. W. Millard & Brother, 17 State Street, are the naval architects in charge.

The proposed vessel will have a length over guards of 210 feet, length between perpendiculars 180 feet, extreme beam over guards 66 feet 2½ inches, beam at deck 45 feet, beam on water line 38 feet, depth amidships 17 feet 6 inches.

Propulsion will be by two direct acting, 2-cylinder, compound, jet condensing steam engines, 19 inches by 38 inches by 28-inch stroke. Steam will be supplied by two Scotch return tube boilers, providing pressure at 150 pounds.

Board to Sell 100 Ships

It has been learned that the Shipping Board is preparing to offer 100 vessels for sale as scrap within the next few days, including eighty old German-built ships and twenty built during the war, which for various reasons are considered unsuitable for operation. They are at the present time tied up at ports along the Atlantic, Gulf and Pacific coasts and some in the Philippines.

Federal Shipbuilding Company Submits Low Bid of \$1,496,000 for Eight Ferryboats for New York

THE Federal Shipbuilding Company, of Kearny, N. J., submitted the low tender for the construction of eight ferryboats for the City of New York at the opening of bids by the Department of Plant and Structures, at 2 P. M., on April 26. The prices submitted provided for the ves-

sels propelled by steam engines and by heavy duty oil engines, the boats to be double-ended, for carrying passengers and vehicles, each having a length over guards of 140 feet, beam over guards 52 feet, beam of hull molded 36 feet and draft of 8 feet 6 inches. The figures submitted were as follows:

Federal	1	2	3	4	5	6	7	8
Steam Engines.....	\$211,000	\$199,000	\$195,000	\$190,000	\$190,000	\$187,000	\$187,000	\$187,000

Sullivan								
Steam Engines.....	210,000	420,000						

While the majority of the vessels will probably be junked for steel, some may be sold with permission for transfer of registry if the purchasers are willing to spend the necessary amounts to put them into condition for operation. The vessels average about 7,000 deadweight tons.

Name of Sun Shipyard Changed

The Sun Shipbuilding Company has announced a change of name to the Sun Shipbuilding & Dry Dock Company. In addition to its building facilities, the yard at Chester, Pa., operates a large floating dry dock.

The New 27,000-Ton Red Star Liner Belgenland

New Red Star Liner Belgenland Arrives on Her Maiden Voyage

THE new 27,000-ton passenger liner *Belgenland* of the Red Star Line which recently arrived in New York on her maiden voyage from Antwerp contains exceptionally elaborate accommodations as well as every convenience and comfort usually found in first class hotels.

The *Belgenland* is a triple screw steamer having a length of 697 feet and a beam of 78 feet 6 inches. She has a passenger capacity of 2,700, of whom 400 can be accommodated in the first cabin. Her propelling machinery is a combination of reciprocating engines on the wing shafts with a turbine on the center shaft similar to the arrangement which has been found very successful on the *Olympic*. Following the latest passenger ship practice which permits of clear and rapid bunkering she has been fitted to use oil as fuel under her boilers.

PUBLIC ROOMS

The public rooms are arranged practically en suite on the "A" deck. The drawing room is the farthest forward and is decorated in lustreless white. Next is the lounge in which the prevailing color is ultra-marine. Bay windows on each side give an unobstructed view of the promenade deck. Following the lounge is a large smoking room containing a fireplace, card tables

and leather upholstered furniture. Back of the smoking room is a veranda sheltered by green latticed walls.

The *Belgenland* differs from other first

rooms with private baths and 8 with private sitting rooms as well. The intercommunicating system allows various combinations of suites to be made. In the bedrooms are numerous novelties in the way of fittings, such as davenports that become beds, buffets that may be converted into washstands, Pullman upper berths for children, heated towel racks, showers, steam heat regulation by thermostats, electric fans, etc.

Smoking Room

class passenger liners in the number of suites, intercommunicating rooms and private baths. On "B" deck there are 32

Philadelphia Lacks Dry Docking Facilities

ALTHOUGH a total of 3,089,000 tons of ships engaged in foreign trade entered the Port of Philadelphia during 1922 in addition to a considerable tonnage engaged in the intercoastal trade, declared Mr. J. Stuart Crandall in addressing the April meeting of the Delaware branch of the American Society of Marine Designers, Philadelphia has only two commercial dry docks capable of handling ships over 350 feet in length.

From this it will be seen, said Mr. Crandall, that Philadelphia has fewer large dry docks per ton of shipping than any other port. This is also true, he said, in regard to the number of smaller dry docks. This is not a balanced condition and it is practically certain that the addition of at least one and perhaps two dry docks for ships over 350 feet long would more than justify the capital outlay.

Steamship Men Opposed to Government Operation

Personal Opinions of Prominent Shipowners Given at Propeller Club Luncheons

THREE prominent shipping executives, namely, Mr. Charles H. Potter, president of the Maritime Exchange and also of the United States Ship Operators' Association, Mr. Alfred Gilbert Smith, president of the American Steamship Owners' Association, and Mr. R. H. M. Robinson, president of the United American Lines, addressed the April meetings of the Propeller Club in New York on the shipping situation. It is to be noted that they all made it plain at the start that they were giving their own personal views and that they were not to be interpreted as representing any organization.

Mr. Potter after calling attention to the great coastwise fleet of some 125 splendid vessels which has been developed under the protection of our coastwise laws declared that unless something is done for our overseas merchant marine in the near future we would become the laughing stock of the world.

SCRAP INEFFICIENT TONNAGE

It would be for the best interests of the Government, shipbuilders, shipowners and ship operators to scrap all undesirable vessels, declared Mr. Potter. We should not, however, sacrifice the whole merchant marine. It may take two or three years with all pulling together to solve the problem. If however the responsibilities of the operators are gradually increased and some arrangement is made whereby special profits can be put into a fund which at the end of three years could apply in part on the purchase price of new ships that would be a solution which would prevent the vessels from falling into the hands of a few.

Mr. R. H. M. Robinson pointed out that after a year of effort to obtain constructive shipping legislation not only was the subsidy bill defeated but the shipowner had been saddled with additional burdens through the ruling prohibiting the sale of liquor on American ships and through the practical limitation of repairs to American shipyards. He also called attention to the recent reduction in seamen's wages in England while the tendency here was distinctly upward.

Mr. Robinson said that the primary purposes of an American merchant marine were to serve as a naval auxiliary, to avoid isolation when ships of other nations are withdrawn in time of war and to insure that American goods can be delivered directly and regularly without transshipment.

OPPOSED TO GOVERNMENT OPERATION

Government operation of a large fleet, said Mr. Robinson, is not in accordance with the principles of American institutions. He thought the effect of such a policy would be to drive more vessels into the intercoastal trade, to cause a transfer of flag, if that is possible and to send the remainder to the scrap heap.

MAKING SHIPPING A NON-PARTISAN ISSUE

Mr. Alfred Gilbert Smith recommended that a non-partisan body be formed to furnish facts and findings upon which a permanent solution of the merchant marine problem can be developed. He pointed out that a solution can be expedited by all maritime interests working together. As President Cleveland once said, it is a condition and not a theory that confronts us.

Our first step, said Mr. Smith, is to see that the policy adopted is one that the Government will adhere to. Our people have

Shipping Board Offers Fleet for Sale Overlapping Services to Be Eliminated Berths Regrouped Into Eighteen Lines

THE United States Shipping Board has announced that it has issued a call for bids for the purchase of passenger and cargo ships from the board's fleet. All bids must reach the board by May 28, 1923. Bidders are asked to enter into an agreement to maintain line service on one or more of 18 routes named by the board, or such other routes, acceptable to the board, as may be proposed by the bidder.

It was announced that the Board has decided to re-group the regular services now being operated by it, through agents, so that each service shall include a reasonably wide range at each terminus, the purpose being to eliminate overlapping or duplication, while at the same time affording larger markets from which and to which to take cargo. As re-grouped, the proposed eighteen services will be as follows:

No.	From	To
1.	North Atlantic.....	United Kingdom (Great Britain and Ireland)
2.	Gulf and South Atlantic.....	United Kingdom (Great Britain and Ireland)
3.	North Atlantic.....	Continental Europe, North of Bordeaux
4.	Gulf and South Atlantic.....	Continental Europe, North of Bordeaux
5.	North Atlantic.....	Continental Europe, South of Bordeaux including all Mediterranean and Black Sea
6.	Gulf and South Atlantic.....	Continental Europe, South of Bordeaux including all Mediterranean and Black Sea
7.	Atlantic Coast and Gulf.....	East Coast South America
8.	Atlantic Coast and Gulf.....	Orient and Philippines
9.	Atlantic Coast and Gulf.....	India and Dutch East Indies
10.	Atlantic Coast and Gulf.....	Australia
11.	Atlantic Coast and Gulf.....	South and East Africa
12.	Atlantic Coast and Gulf.....	West Africa
13.	Pacific Coast.....	East Coast South America
14.	Pacific Coast.....	West Coast South America
15.	North Pacific.....	Orient and Philippines
16.	South Pacific.....	Orient and Philippines
17.	Pacific Coast.....	Europe
18.	Pacific Coast.....	Australia

The board announces that the bidder may make such offers as he desires; but every bidder shall include in his offer a guarantee to operate the ships to be purchased for a specified period over the routes selected by him, and not elsewhere. The bidder must specify the names of the ships he desires to purchase; the price offered and terms of payment; the route over which he will undertake to maintain service; the charter, frequency, and extent of such service; period of time for which he will

guarantee maintenance of service; and the nature and terms of the guarantee.

So far as possible the bidder shall select vessels now being operated on routes included in the route for which he makes his bid. Bidders are, however, free to specify vessels from the board's laid-up fleet, or even those in operation on other routes.

The bidder may make his bid upon the understanding that the board, upon acceptance of any tender and the making of a contract with adequate guarantee for maintenance of service, will agree not to operate in competition directly or indirectly, government-owned ships, while adequate service is maintained; that it will neither charter nor sell, for operation on that route, at a price lower than current commercial charter rates or world market prices for unrestricted operation.

Prospective bidders are invited to come

to Washington to confer with the Commissioners of the United States Shipping Board who, together with the officials of the United States Shipping Board Emergency Fleet Corporation, will be ready at all times to aid responsible bidders to formulate bona fide bids.

Information is available of the operating costs of the various classes of board vessels, and the financial results of existing services.

The board reserves the right to reject any and all bids.

Cory Extends Service to Boston District

Chas. Cory & Son, Inc., of New York, manufacturer of ships' telegraphs, marine signaling, communicating and lighting equipment has opened an office in Boston at 88 Broad street, in charge of A. E. Sargent, well-known electrical engineer, who for many years was connected with the Bethlehem Shipbuilding Corporation at the Fore River plant.

Combustion Engineering Corporation to Handle Uehling Interests in Canada

The Combustion Engineering Corporation, Ltd., and the Uehling Instrument Company have recently entered into an agreement whereby Uehling interests in the Dominion of Canada and Newfoundland will be handled exclusively by the Combustion Engineering Corporation, Ltd., with principal offices located in Toronto, Montreal, Winnipeg and Vancouver.

Correction

In the description of the electric ferry-boat *Poughkeepsie* published in our March issue the name of the manufacturer of the reduction gears and flexible couplings installed in the vessel was inadvertently omitted. The gears and couplings were the Falk reduction gears and Falk-Bibby flexible couplings manufactured by the Falk Company, Milwaukee, Wis.

Foreign Shipping and Shipbuilding Activities

German Shipbuilding in 1922 Analyzed Oil Burning Installations and Electric Drive Receiving Attention of French Shipowners

By Our Paris Correspondent

VESSELS under construction in German yards in 1922 for both German and foreign account totalled 1,353, of 1,495,700 gross tons, a decrease of 14.9 percent from the 1921 figure, according to the Statistische Reichsamt, forwarded to the Department of Commerce by Consul O. N. Nielsen, Berlin; but tonnage completed during the year was 64.5 percent greater in 1922 than in 1921. The number of ships completed in 1922 was 648.

Of the total under construction for German accounts in 1921, 1,086 vessels, of 1,667,000 tons, were seagoing merchant ships; in 1922 this class of vessel being built for German companies dropped to 407, with a total tonnage of 1,171,600, a decrease in tonnage of 29.6 percent.

The German tendency toward construction of motorships is shown by the fact that in 1920 motorships aggregating 73,000 tons were under construction; in 1921, 135,000 tons; and in 1922, 121,000 tons.

In both 1921 and 1922 there were under construction in foreign yards for German accounts between 40,000 and 50,000 gross registered tons. These consisted of orders placed in the hands of former German companies in Danzig and Memel before the separation of those districts from Germany, and now represent tonnage intended for the reparations account.

In 1920 about 67 percent of the vessels completed came from the North Sea yards; in 1921, 60 percent; and in 1922, 56 percent. The Baltic Sea yards, on the other hand, show increasing business in 1921 and 1922, in the latter year delivering 34 percent, as compared with 33 percent in 1921 and 29 percent in 1920. Inland shipyards built approximately 12,000 tons in 1920, 72,000 tons in 1921, and 31,000 tons in 1922.

Norwegian Course and Speed Recorder Invented

According to the Department of Commerce, a patent has recently been granted in Norway for an apparatus that by the aid of an electric clock connecting the compass, log and clock will automatically register the speed, course and time.

This invention, which is very small and compact, can be installed anywhere on board ship enabling the officers to give incontrovertible proof of the dispositions of the ship.

Italy to Build Big Liners

ROME, Italy (Special).—As a result of the protective policy adopted by the new Mussolini Government, the Italian shipbuilding firm of Tosi Shipyards Company has received a contract for two ocean liners of about 20,000 tons each. These two ships are for the account of the Lloyd Sabaudo of Genoa, which has had many of its former ships, notably the *Conte Rosso* and *Conte Verde*, built in Great Britain. Italy's protective policy for shipbuilding is expected to do a great deal for that industry; in fact, satisfactory results have already been noted.

FRANCE has noted the general movement in the various maritime countries in favor of the adoption of oil-burning under boilers. French shipowners now realize the advantages and economy to be obtained with oil-burning vessels in such matters as a reduced crew, greater bunkering facilities, quicker turn around, less wear on the boilers and other advantages such as general cleanliness of passenger accommodations.

The commercial success of the *Paris*, the largest French vessel afloat, which was placed in service by the Compagnie Generale Transatlantique in June, 1921, has fully confirmed the general opinion in this respect and this company is therefore considering, with more and more favorable attention the conversion of their second largest liner, the *France*, to oil-burning.

CONVERSION OF THE FRANCE

It is already ascertained that such a transformation would result in a reduction in personnel of no less than 160 men. In addition to the saving in wages there must be added the saving in fuel consumption and also the profit of making one more return voyage per annum. Taking into account these various advantages it is estimated that the conversion of the *France* to an oil-burner, which would involve an expenditure of about 6 million francs, would result in a total saving of about 1 million francs per year.

As the *France* is only 11 years old the French Line have very good reason for this conversion and there is little doubt but that

First Large French Cargo-Motorship Nearing Completion

The first big French vessel to be fitted with Diesel propulsion is the cargo-motorship *Camranch* which is being completed by the Chantiers de la Loire at Nantes for the account of the Chargeurs Reunis. This vessel is of 11,700 tons deadweight. Her propelling machinery consists of two Sulzer four-cylinder two-cycle marine engines, each developing 1,700 shaft horsepower, which were built at the Winterthur works of Messrs. Sulzer Brothers. In addition to the main engines, two 410 brake horsepower four-cylinder Sulzer two-cycle engines are provided to drive dynamos at 200 revolutions per minute.

France to Build Six Submarines

PARIS, France (Special).—Six new submarines of 1,000 tons displacement each have been ordered by the French Admiralty. They will be equipped with twin engines of 2,000 horsepower which have been ordered from the Societe Generale Electrique of Nancy. It is reported that six additional submarines have been authorized but, so far as can be ascertained, the contracts have not yet been placed.

a decision will be made to go ahead with this work in the near future.

In case the conversion to oil-burning should be decided upon by the owners, it would doubtless be carried out by the end of 1923 when a general overhaul of the boilers is due in order to comply with the requirements of the Bureau Veritas. It is estimated that the liner would only have to be laid up for about 5 months.

CONTRACT WILL PROBABLY GO TO ENGLISH FIRM

As regards the system of oil burning which would be adopted on the *France*, it is a question whether any of the few French firms who specialize in this equipment would be in a position to offer sufficient guarantees of reliability to secure such a big order and it is hinted that this work might be placed with the Wallend Slipway Engineering Company, who supplied the oil burning installation of the *Paris*. It may be pointed out that this British firm has supplied most of the oil-burning equipment on French vessels.

Up to the present time there are but two firms in France which are in a position to install oil burning installations of their own system under satisfactory conditions: these are the Chantiers de la Gironde, who are now completing the steamship *Aramis* built to the account of the Messageries Maritimes, and the Forges et Chantiers de la Mediterranee, which have just supplied the oil burning equipment for four passenger steamers of the *Mustapha II* type built for the account of the Department of Mercantile Marine (the *Gouverneur-General-Tirman*, *Gouverneur-General-Cambon*, *Gouverneur-General-Lepine* and *Gouverneur-General-Laferriere*). The Forges et Chantiers de la Mediterranee have also carried out the oil burning installation on the two sister ships *Guaraja* and *Ipanema*, built for the account of the Societe Generale des Transports Maritimes à Vapeur, Marseilles.

ELECTRIC DRIVE

These two steamers are the first and so far the only French vessels equipped with turbo-electrical propulsion. These ships have a displacement of 8,000 tons and a deadweight carrying-capacity of 5,130 tons at 23 feet draft. (Length, 360 feet 2 inches; breadth, 46 feet 2 inches; depth, 26 feet 3 inches.) The propelling machinery consists of two turbo-alternators supplied by the Etablissements Sautter-Harlé of 1,000 kilowatts running at 3,000 revolutions per minute. The reduction is 24, the propeller revolutions per minute being 123. Two speeds are provided for, namely, for cargo business, 10 knots, and for passenger business, 13 knots.

FRENCH LINE CONSIDERING ELECTRIC DRIVE

In connection with the future adoption of electric drive by French shipowners it is learned on good authority that the French Line is considering this mode of propulsion for their new passenger steamer *De Grasse*, which is under construction at Birkenhead at the yards of Messrs. Cammell Laird and Company.

Marine Construction News of the Month

Ship Contracts—New Ship Concerns and Shipyard Improvements—Terminal Projects—Government Contracts

SHIPBUILDING AND REPAIRS

Rudder Replaced, Portland, Ore.—The steamer Flavel was drydocked at Portland to have her rudder replaced.

Shipyard Busy, Oakland, Cal.—The Moore Shipyard is fitting out the salmon packers' fleet for the summer season.

Steamer Drydocked, Seattle, Wash.—The damaged steamer Sagadahoc was placed on drydock at Seattle for hull repairs.

Conversion of Tanker, San Pedro, Cal.—The British tanker Lumina is being converted from a coal to an oil burner.

Steamer Drydocked, Portland, Ore.—The Japanese steamer Yoshida Maru has been drydocked for cleaning and painting.

Vessel Overhauling, Oakland, Cal.—The steamer Bessie M. Hanlon has been placed on the Hanlon ways for an overhauling.

Overhauling Steamer, Portland, Ore.—Steamer Hawaiian, of the American-Hawaiian fleet, has been drydocked for an overhauling.

Minor Repairs, Mobile, Ala.—The steamship La-bette was awarded to the Alabama Dry Dock and Shipbuilding Company for minor repairs.

Low Bidder, San Francisco, Cal.—The Crowley Shipyard was low bidder for repairs to the British steamer Berengar, with a tender of \$800.

Vessel Drydocked, Portland, Ore.—The Columbia River Packers' Association cannery vessel has been placed on drydock at Portland for repairs.

Tanker Drydocked, San Francisco, Cal.—The Standard Oil tanker W. S. Miller has been placed on the ways of the Bethlehem Shipbuilding Company.

Vessel Overhauled, San Francisco, Cal.—The tanker Mursa was awarded the Bethlehem Shipbuilding Corporation for overhauling, to enter the oil trade.

Extensive Reconditioning, San Francisco, Cal.—The Bethlehem Shipbuilding Corporation received the contract for overhauling the interior of the yacht Edyth.

Repairs to Steamboat, Baltimore, Md.—The Redman & Vane shipyard was awarded the work of docking and repairing the sidewheel steamboat E. Madison Hall.

Overhauling Steamer, Portland, Ore.—The Shaver Transportation Company's steamer No Wonder has been placed on the docks of the Portland Shipbuilding Company.

Miscellaneous Repairs, Philadelphia, Pa.—The steam pilotboat Philadelphia has been taken to the Philadelphia Ship Repair Company's yards for miscellaneous repairs.

Steamer Fitted, Baltimore, Md.—The Shipping Board awarded the fitting of the steamer Deer Lodge to carry cattle to Lewis Waggner & Company, on a bid of \$6,700.

Diesel Engines Fitted, Oakland, Cal.—The steamer Magunkook, of the Oceanic Steamship Company, was awarded to the Moore Drydock Company for the installation of Diesel engines.

Flush Deck Barges, Nashville, Tenn.—U. S. Engineer Office, Nashville, is in the market for the rental of three flush deck barges, steel or wood, from 200 to 300 tons capacity.

General Repairs, San Francisco, Cal.—The schooner Bangon and the steamer Whitney Olson have been placed on the Bethlehem drydocks for cleaning, painting and general repairs.

Miscellaneous Repairs, Mobile, Ala.—The Light-house tender Sunflower was awarded to the Alabama

Dry Dock and Shipbuilding Company for scraping, painting and other miscellaneous repairs.

Cleaning and Painting, Boston, Mass.—The Nantucket, nautical school ship, has been moved to the Boston Navy Yard for cleaning and painting, prior to departure about May 1 on the annual cruise.

Vessel Repairs, Seattle, Wash.—The steamship Wallingford, recently bought from the Shipping Board by the McCormick Steamship Company, has been shifted to a Seattle drydock for overhauling.

General Repairs, Oakland, Cal.—The Hanlon Drydock and Shipbuilding Company received the contract for general repairs, cleaning and painting of the Hart-Wood Lumber Company's steamer Solano.

Painting, etc., San Francisco, Cal.—The new ferryboat Hayward was taken to the ways of the General Engineering and Drydock Company to be painted, bulwarks removed and to have her engines overhauled.

Vessel Drydocked, Oakland, Cal.—The Hanlon Shipbuilding and Drydock Company was awarded the contract for drydocking, recaulking and other work on the schooner Honoipu, recently purchased by N. H. Hickman.

Vessel Repairs, Sparrows Point, Md.—The Bethlehem Shipbuilding Corporation has been awarded the work of repairing the West Arrow, at a price of \$4,196. The same company was awarded the docking of the West Haven.

Seattle Shipyard Activities.—The following repairs were awarded to Seattle shipyards: Steamship Admiral Evans, for reconditioning; steamship H. F. Alexander, to ship new propellers, and steamship Seapora, for overhauling.

Tailshaft, Etc., Philadelphia, Pa.—The William Cramp & Sons Ship and Engine Building Company has completed a contract which consisted of installing a new tailshaft and propeller on the gunboat Bravo, of the Mexican Navy.

Extensive Reconditioning, West Coast.—The freighter Meriden, recently sold by the General Steamship Corporation to the E. K. Wood Lumber Co., is to undergo extensive reconditioning to fit her for the coastwise lumber trade.

Steamboat Converted, Port Blakely, Wash.—The Johnson Shipyard, Port Blakely, has been converting the steamboats City of Angeles and Puget of the Puget Sound Navigation Company into modern ferryboats. Price \$30,000 each.

Refitting for Service, Oakland, Cal.—The tank motorship Nuuanu, of the Philippine Vegetable Oil Company, was placed on the ways of the Hanlon Drydock and Shipbuilding Company to undergo an overhauling, preparatory to being placed in service again.

Contract Awarded, San Francisco, Cal.—With a bid of \$1,188, the General Engineering and Drydock Company has been awarded the contract for repairs to the California and Oregon Lumber Company's steamer Brookings, formerly the Shipping Board steamer Cowiche.

Contracts Awarded, Seattle, Wash.—The Todd Drydocks were awarded the following contracts: Shipping Board tanker Lubrico, a fishing schooner, a Government-owned brigantine, fisheries steamship, a Puget Sound tugboat, an ocean-going tug, and a lighthouse tender.

Preparation for Service, Sparrows Point, Md.—Previous to being prepared for service, the sidewheel steamer Majestic, bought at Washington by the Annapolis and Claiborne Ferry Company, has been placed in the upper yard of the Bethlehem Shipbuilding Corporation.

Shipyard Activities, Oakland, Cal.—The Moore & Scott shipyard, Oakland, is very busy as a result of having been awarded the following vessels: The ferryboat Cazadero, drydocking; schooner City of Sydney, repairs; two United States submarine chas-

ers, the Vaughn and Cygan, overhauling; and the Lake Cayuga and Lake Francis, conversion to oil and lumber schooners.

Low Bidder for Barge, San Francisco, Cal.—Bethlehem Shipbuilding Corporation, San Francisco, submitted the lowest tender for the construction of a 12,000-barrel towing barge for the Standard Oil Company of California, with a price of \$219,775 and four and one-half months.

Voyage Repairs, Oakland, Cal.—At the opening of bids for voyage repairs to the Pacific Mail liner President Taft the Moore Drydock Company was low bidder with \$7,264. The other bids were: Bethlehem, \$7,840; United Engineering Company, \$8,199, and General Engineering, \$10,865.

Contracts Awarded, Mobile, Ala.—The Alabama Dry Dock & Shipbuilding Company, Mobile, received the following contracts: Steamship Afoundrias, repairs to engine room, pipe lines, boilers, etc.; tug Jim Sid, cleaning and painting; and tug Major Carl A. Lehr, for miscellaneous repairs.

Cardboat Launched, Sparrows Point, Md.—The first of two huge steel cardboats, under construction for the Baltimore and Ohio Railroad, has been launched from the Sparrows Point plant of the Bethlehem Shipbuilding Corporation. The float is 285 feet long, 37 feet 6 inches beam and 10 feet 6 inches draft.

Miscellaneous Repairs, San Francisco, Cal.—The Bethlehem Shipbuilding Corporation was awarded the following contracts: The Standard Oil tanker Colonel E. L. Drake, general repairs; and the Virginian of the American-Hawaiian intercoastal fleet overhauling of tail shaft and renewal of propeller blades.

Reconditioning Work, Oakland, Cal.—The Hanlon Shipbuilding Company, Oakland, was awarded a large reconditioning job on the lumber carrier Catherine G. Sudden. The Star of Scotland and the Pacific Mail steamer Corinto have also been placed on the ways of the Hanlon for general overhauling.

Scout Cruiser Launched, Philadelphia, Pa.—The 550-foot scout cruiser Trenton, of 90,000 horsepower, has been launched at the shipyard of William Cramp & Sons. She is the second of five scout cruisers being built at the Cramp shipyard for the United States Navy and is expected to make a speed of thirty-three knots.

General Overhaul, Brooklyn, N. Y.—The contract for the drydocking and general overhauling of the steamship Natirar has been awarded to James Shewan & Sons at a price of \$36,810. The proposals submitted were as follows: Shewan, \$36,810; Robins, \$38,850; Crane, \$39,890; Morse, \$42,182; Federal, \$48,185.

Double Launching, Baltimore, Md.—Charles L. Rohde & Sons Company recently held a double launching of a cardboat for the Atlantic Transport Company, 240 feet long, 34 feet wide and 9 feet 6 inches molded depth, and a lighter for the Southern Railway Company, of Norfolk, 125 feet long, 30 feet wide and 8 feet 6 inches deep.

Vessel Overhauling, Portland, Ore.—The late Rear Admiral Peary's famous vessel, the former Arctic explorer Roosevelt, is being overhauled to go in service as a towing vessel. The most modern towing apparatus obtainable is being installed on board the Roosevelt, which is to be utilized in the towing of lumber barges between Puget Sound and California.

Fire Damage, Panama City.—The coastwise steamer Tarpon, operated by the Pensacola, St. Andrews and Gulf Steamship Company, between Pensacola and Mobile and Carabelle was badly damaged by fire on March 23. She was moored at Panama City docks and damage was covered by insurance, it is said. The Tarpon has been in service more than twenty years.

Conversion to Passenger Steamer, Baltimore, Md.—The Baltimore and Carolina Steamship Company

has announced that the Mary Weems, now being used on the freight run of the line, will be put in the Baltimore shipyards shortly for the beginning of work which will make her a passenger ship, to accommodate 200 first class passengers and 50 second class. J. L. Doten, Charleston, S. C., representative.

Shipyard Activities, San Francisco, Cal.—The Bethlehem Shipbuilding Corporation has been awarded the following contracts: Work of retubing condensers, feed water heaters, and rebuilding anchor windlass on the Compagnie Du Boleo's steamer Providencia; reconditioning Associated Oil Company's tug Arabs, price \$21,795; and the O. A. Smith, lumber carrier, for cleaning, painting and overhauling.

Various Contracts, Baltimore, Md.—The Charles L. Rohde & Sons Company received the following contracts: Tugs Wilcox, of Toledo, Ohio, Mary C. McNally and Annie, for overhauling; and barge John J. McNally, for similar work. The German steamer Hensen was floated after replacing a broken propeller blade and having her hull painted. The Vittorio Emanuele III. has been placed on the lower dock of the company.

Contract Awarded, Oakland, Cal.—The Army Transport Service has awarded the contract for reconditioning of the transport Grant to the Moore Drydock Company, as low bidder, the work consisting of painting and fixing first cabin quarters and installation of accommodations for twenty-four passengers in the second class quarters of the vessel. The Grant has been at the Moore ways for cleaning, drydocking and painting, on a former bid.

Repair Job, Brooklyn, N. Y.—The Robins Drydock & Repair Company, of the Todd Shipyards Corporation, Brooklyn, N. Y., was awarded the contract for repairing the American-Hawaiian freighter Texan, which sustained heavy bottom damage as the result of grounding on Block Island. The bids received were as follows: Robins, \$96,790; Morse, \$144,496; Shewan, \$159,000; Bethlehem, \$172,600; Newport News, \$181,300; Sun Shipbuilding, \$199,615.

Diesel Yacht Construction, Seattle, Wash.—The Blanchard Boat Company is constructing, in the plant of the Tregoning Manufacturing Company on Salmon Bay, the full Diesel-powered yacht Samona, which will be the most palatial craft of her type on the Pacific. The yacht, which is building for W. J. Hole, capitalist and sportsman of Arlington, Cal., will be a triple-screw yacht, each screw being driven by a 100-horsepower, six-cylinder Diesel engine, maintaining a speed of 13 knots. The vessel will be 115 feet long and 18 feet beam, heated by electricity and having all latest improvements.

Tank Steamer Repairs, Brooklyn, N. Y.—At the opening of tenders for extensive repairs to the 6,666 gross ton tank steamship Pennsylvania, of the Texas Oil Company, the Robins Drydock & Repair Company, of the Todd Shipyards Corporation, Brooklyn, N. Y., was successful bidder with a price of \$167,000. The Pennsylvania recently went ashore on the Nicaraguan coast and sustained considerable bottom damage, after which she was drydocked at Mobile for survey. The following are the proposals received: Robins, \$167,000; Newport News, \$175,000; Morse, \$176,000; Alabama, \$179,488; Jahncke, \$263,000.

Reconditioning Work, West Coast.—The Moore Drydock Company was low bidder for work of drydocking, cleaning and painting the Pacific Mail steamer Point Bonita, chartered by the E. K. Wood Lumber Company. The tenders were as follows: Moore's, \$1,299; Bethlehem, \$1,525, and Hanlon's, \$1,919. Bids opened for repairs to the United States Army transport Grant were: Moore's, \$6,798; Bethlehem, \$6,996; for cleaning, drydocking and painting. The Moore Company was also low bidder for engine and boiler repairs to the transport Grant, with a price of \$9,878, against the Bethlehem Shipbuilding Company's tender of \$9,954.

Towboat Hull, Jeffersonville, Ind.—The Howard Shipyards & Dry Dock Company, of Jeffersonville, Ind., with a price of \$19,737, was low bidder for the construction of a steel hull for the towboat Elinor, at the opening of tenders by the United States Engineer Office, Rock Island, Ill., on April 12. The boat is to be of the sternwheel type, having a molded length of 125 feet 4 inches, molded breadth 27 feet, constructed with five transverse watertight bulkheads. The bids were: Howard Shipyards & Dry Dock Company, \$19,737; Dubuque Boat & Boiler Works, \$20,000; Dravo Contracting Company, \$25,600; Nashville Bridge Company, \$25,900; Charles Ward Engineering Works, \$27,200.

Contracts Awarded, Mobile, Ala.—The Alabama Dry Dock and Shipbuilding Company has been awarded the following contracts: Shipping Board steamship Hugoton, cleaning, painting, general overhauling of machinery, etc.; Mississippi-Warrior Service Towing steamer Demopolis, repairs to propellers, renewing rudders, machinery job and several other miscellaneous repairs; steamship Shreveport, overhauling machinery, caulking decks, scraping, painting, etc.; steamship Halfway, miscellaneous repairs; steamship Tuxpanoil, repairs; tug Hulver, extensive repairs; steamship Bayou Chico, repairs; schooner Maid of Scotland, cleaning, painting and examination, and oil tanker San Leonardo, of the Eagle Oil Transport Company, Ltd., for examination.

SHIPYARDS AND DRYDOCKS

Dismantling Yard, Baltimore, Md.—The Atlantic Wrecking Company, of which Victor M. Jarrett is president and general manager, will establish modern facilities for dismantling ships at Baltimore on the waterfront of Curtis Bay. About \$60,000 will be expended to clear the site of old grain elevator buildings purchased from the Baltimore & Ohio Railroad, after which the wrecking facilities will be installed, the capacity to be four steamships at one time.

Shipyard, Lower California.—According to Bartley F. Yost, American Consulate at Guaymas, Sonora, Mexico, American interests have asked permission from the Secretary of Communications to install at Santa Rosalia, Lower California, a shipyard for constructing vessels up to 5,000 tons, destined for coastwise and high seas traffic. The company is requesting certain franchises, and states that as soon as the vessels are completed it intends to use them for its own account in open competition with foreign steamship companies.

PORT IMPROVEMENTS

Harbor Improvements, Monterey, Cal.—City plans election to vote on \$200,000 bonds for harbor improvements, dredging, fill, etc.

Piling, Brokaw, Wis.—L. A. De Guere, engineer, Wisconsin Rapids, is taking bids for 800 tons Lackawanna steel piling, for Wausau Paper Company.

Grain Elevator, Oswego, N. Y.—An appropriation of \$1,307,000 has been made for the completion of the grain elevator and terminal on the State Barge Canal at Oswego.

Grain Elevator, Goderich, Ont.—Western Canada Flour Mills, 293 McPherson avenue, Toronto, plans 750,000-bushel addition to grain elevator, reinforced concrete. \$250,000.

Canal, Etc., New London, Wis.—City Council has appropriated \$750,000 to construct canal and drainage system to join Wolf and Embarrass Rivers. C. J. Thompson, clerk.

Dredging, North Carolina.—State Fish Commission, Raleigh, plans to dredge and deepen various inlets to sounds in North Carolina. \$500,000. J. K. Dixon, Trenton, chairman of Commission.

Pier, San Diego, Cal.—The city voted \$495,500 bonds for completion of municipal pier No. 2, including apron wharf, transit shed, paving trackage and equipment. F. A. Rhodes, city engineer.

Harbor Facilities, Troy, N. Y.—Harbor & Dock Commission, Troy, has \$1,250,000 available for harbor facilities. Plans municipal terminal, \$350,000. M. L. Murray, 16 First street, president.

Dredging, Buffalo, N. Y.—The Empire Engineering Company, Inc., North Tonawanda, received the contract for dredging Buffalo Inner Harbor to completed contract depth for maintenance of channel, at a price of \$0.345 per cubic yard.

Levees, Monroe, La.—G. B. Lambert Company awarded the contract for 1,000,000 cubic yards of levee work on Mississippi River, near Monroe, to W. E. Callahan Construction Company, Great Southern Life Building, Dallas, Tex. \$250,000.

Canal to Be Opened, New Orleans, La.—The new Inner Harbor Navigation Canal will be opened formally at the close of the annual convention of the National Foreign Trade Council in New Orleans, May 2 to 4. This canal connects the Mississippi

River with Lake Ponchartrain and transforms great tracts of interior lands into waterfront property suitable for purposes of commerce and industry.

City Wharf, Norwalk, Conn.—Sealed proposals were received by John H. McMahon, chairman, City Hall, Norwalk, Conn., for alternate bids for the construction of about 200 lineal feet of concrete and creosoted lumber wharf with appurtenances, on April 2.

Grain Elevator, Goderich, Ont.—Goderich Grain Elevator & Transit Company is having plans prepared for a reinforced-concrete grain elevator, 1,000,000 bushel capacity, on harbor. Price, \$250,000. J. H. Trommhauser, 69 Adelaide street, East, Toronto, engineer.

Miscellaneous Supplies, Memphis, Tenn.—Sealed proposals were received by the Mississippi River Commission, First and Second Districts, Custom House, Memphis, on April 23, for furnishing and delivering steel bars, wire fencing, machine bolts and insulating paper.

Concrete Wharf, Etc., New Orleans, La.—Sealed proposals were received by the Board of Commissioners of the Port of New Orleans, Suite 200, New Court Building, on April 5, for concrete wharf, chain walls and column footings for shed at Calborne Avenue Landing.

Canal, Lakeland, Fla.—Lake Parker D. D., canal between Lake Parker and Lake Boney. S. T. Buchannan & Son, Lakeland, received the contract for 50,000 cubic yards of earth and 40,000 cubic yards of rock excavation, 200 cubic yards reinforced-concrete. Price \$0.33½ earth and rock.

Flood Gate, Etc., Blytheville, Ark.—Poinsette Company will soon take bids for flood gate and navigation lock, \$200,000, and also plans complete flood protection and river control system, ultimate cost, \$5,000,000. Pride & Fairley, Blytheville, engineers.

Piling, New Orleans, La.—Sealed proposals were received by the Board of Commissioners of the Port of New Orleans, Suite 200, New Court Building, on April 26, for furnishing 7,500 pieces of green piling in 50 and 75-foot lengths, according to Dock Board specifications. Requisition ED-13352.

Contract Awarded, Houston, Tex.—Anderson Clayton & Company, Mason Building, has awarded the following work to J. B. Townsend, Houston, at a price of \$750,000: warehouses, reinforced-concrete woodpile foundations, cotton compress, 600-foot wharves, concrete construction, also dredging channel.

Bulkhead, Etc., Chicago, Ill.—The Great Lakes Dredge & Dock Company, 104 South Michigan avenue, was awarded the contract by South Park Commissioners, 57th street and Cottage Grove avenue, for bulkhead from 12th to 20th streets, \$1,164,310; 1,000 foot extension to bulkhead at 23rd street, \$95,000.

Contract Awarded, Baltimore, Md.—The contract for the construction of the four million bushel grain elevator to be built for the Baltimore & Ohio Railroad at Locust Point, to replace its two elevators destroyed by fire there last July, has been awarded to M. A. Long Construction Company, of Baltimore. Price, \$3,000,000.

Dredging Contract, Mays Landing, N. J.—The Commerce & Navigation Department, State House, Trenton, awarded the contract for dredging 57,142 square yards of main channel, Absecon Inlet, Mays Landing, to Hill Dredging Company, Atlantic and Somerset streets, Atlantic City. Price, \$0.35 per square yard. Total price, \$19,999.70.

Levees, Yuba City, Cal.—Reclamation District 1660, State Reclamation Board, Forum Building, Sacramento, Cal., awarded the contract for 13-mile levees, varying 12 to 22 feet in height, 2,600,666 cubic yards of clamshell work, and 1,110,000 cubic yards of long boom dredger work, Yuba City, to Callahan Construction Company, City National Bank, Wichita Falls, Tex. Price, \$915,000.

Grain Elevator, Baltimore, Md.—Bids will be received by the Baltimore & Ohio Railroad, Baltimore and Charles streets, Baltimore, for grain loading pier, merchandise pier, storage bins, steel and reinforced concrete, 3,000,000 to 4,000,000 bushel capacity, Locust Point. Price, \$3,500,000. J. S. Metcalfe, 108 South La Salle street, Chicago, architects. L. P. Kimball, Engineering Building, of Baltimore & Ohio Railroad, engineer.

Contract Awarded, Ft. Worth, Tex.—The Western Engineering Company, Dallas County State Bank Building, Dallas, was awarded the contract by Ft.

Worth Elevators Company, N. P. Anderson Building, for one 750,000 bushel elevator and storage tank, 54 by 72 by 192 feet head house with thirty-six 23 by 100 feet storage tanks, all concrete, four 2,500 bushel straight hopper scales, six main elevator legs with 30-inch lift belts, two receiving legs, two shipping legs, one serving leg, and one transfer leg, two large Carter disc separators, one 1,500-bushel hour capacity clipper and scourer, two Richardson auto sacking machines and scales. Price, \$1,000,000.

GOVERNMENT WORK

Scows, Wilmington, Del.—U. S. Engineer, Wilmington, plans to purchase two wooden dump scows.

Repairing Jetty, Galveston, Tex.—U. S. Engineer plans to repair building and extend jetty at Sabine.

Superstructure, Dunkirk, N. Y.—U. S. Engineer plans stone superstructure on breakwater at Dunkirk.

Dredging, Galveston, Tex.—U. S. Engineer plans dredging Houston Ship Channel at Vinces Bayou and Basin.

Dredging, Washington, D. C.—U. S. Engineer, 250 Old Land Office Building, plans dredging in Potomac River.

Gate Tracks, Huntington, W. Va.—Gate tracks at Dam 13, Ohio River, are planned by U. S. Engineer, Huntington.

Barges, Jacksonville, Fla.—U. S. Engineer, Jacksonville, plans to purchase three steel barges for dredge Mallery, Ohio River.

Dredging Pump, Jacksonville, Fla.—Bids were received by U. S. Engineer, Jacksonville, up to April 20, for a dredging pump.

Dredging, Claiborne Harbor, Md.—U. S. Engineer Office, Baltimore, received sealed proposals on April 30, for dredging in Claiborne Harbor, Md.

Dredging Bids Rejected, New York, N. Y.—U. S. Engineer, 616 Army Building, has rejected bids opened on March 2, for dredging in Shrewsbury River, N. J.

Boilers, Florence, Ala.—Bids were received on April 27, at the office of the U. S. Engineer, Florence, for installing steam boilers, etc., on the U. S. Towboat General John Coffee.

Steel Gates, Nashville, Tenn.—Sealed proposals were received by U. S. Engineer Office, Nashville, on April 25, for steel gates for Lock 8, Cumberland River. Further information on application.

Dredging, Wharves, Etc., Pearl Harbor, H. T.—Specifications 4798—Bureau of Yards and Docks, Navy Department, Washington, D. C., plans dredging, wharves and piers at submarine base. Bids opened at local yard.

Fuel Oil, Philadelphia, Pa.—U. S. Engineer, 815 Witherspoon Building, awarded the contract for furnishing 40,000 barrels of fuel oil for vessels in Philadelphia, to Crew Levick Company, 111 North Broad street. \$73,750.

Rock Removal, Etc., New York, N. Y.—U. S. Engineer, Army Building, 39 Whitehall street, awarded Arundel Corporation, 2 Pratt street, Baltimore, Md., the contract for dredging and rock removal in East River. \$704,387.

Painting, Etc., Vessel, Staten Island, N. Y.—Sealed proposals were received by the Superintendent of Lighthouses, Third District, Staten Island, N. Y., on April 2, for docking, cleaning and painting Relief Light Vessel No. 78.

Drydocking, Etc., Staten Island, N. Y.—Sealed proposals were received at the office of Superintendent of Lighthouses, Third District, Staten Island, N. Y., on April 2, for drydocking, cleaning and painting U. S. Lighthouse Barge No. 2.

Cylinder Valves, Etc., Florence, Ala.—U. S. Engineer Office, Florence, received sealed proposals on April 20 for furnishing and delivering six sets of cylinder valves, operating mechanism for the same, etc., for the navigation lock of Wilson Dam.

Superstructure, Detroit, Mich.—Sealed proposals will be received by U. S. Engineer Office, Detroit, Mich., until 11 A. M., Eastern Standard Time, May 3, 1923, for construction of concrete superstructure on west center pier, St. Mary's Falls Canal. Further information on application.

NEW INCORPORATIONS

The Submarine Signal Corporation, capital \$9,000,000, chartered in Delaware.

The Montrose Steamship Corporation of New York, capital \$250,000, chartered under Delaware laws.

The American Export Corporation, of Manhattan, has increased its capitalization from \$25,000 to \$100,000.

The Niagara Ferry & Transportation Company has increased its capitalization from \$25,000 to \$300,000.

William Grixcom Cox, capital \$500,000, incorporated under Delaware laws, to do business as ship brokers.

The Hammond Steamship Company, of Wilmington, Del., capital \$1,000,000, to do business as builders, chartered under Delaware laws.

Ralph Steamship Company, of Brooklyn, capital \$100,000, chartered at Albany. Incorporators: L. N. and J. A. Martin and P. J. Dobson.

The Transit Forwarding Company of Buffalo, capital \$20,000, chartered at Albany. Incorporators: E. B. and A. B. Black and D. L. Sprissler.

U. S. & Levant Steam Navigation Company, capital \$250,000, chartered at Albany. Incorporators: J. J. Binder, S. Brander and R. Frackman.

The Palestine & Oriental Steamship Corporation of Manhattan, capital \$20,000, chartered at Albany. Incorporators: E. Rosen and J. & A. Haber.

Rotary Navigation and Transportation Company of Manhattan, capital \$50,000, chartered at Albany. Incorporators: M. M. Miller and J. W. Bagley.

United States & China Steamship Co., Inc., capital \$12,000,000, to operate between New York and Far East ports. David L. Baumgarten, president.

The Olympus Steamship Corporation, of Manhattan, capital \$10,000, chartered at Albany. Incorporators: W. S. Auld, J. J. Binder and S. Brander.

T. A. Kyle Company, of the Bronx, shipyard, capital \$50,000, incorporated under New York laws. Incorporators: T. A. and J. Kyle, and G. L. Bergen.

The Florence B. Phillips Shipping Corporation of Manhattan, capital \$50,000, incorporated at Albany, to do general lighterage business. Incorporators: J. Potts, E. C. Bould, and G. Palmer.

Russian-American Volunteer Fleet, capital \$10,000, chartered under Delaware laws to operate boats. Incorporators: E. C. Barton of Yonkers, and Martha Kobloff and Ralph F. Kane.

Warner Transport and Trading Company; principal place of business, Miami; capital stock, \$20,000; limit of indebtedness, \$1,000,000. General nature of business, the transportation for hire of passengers and of all kinds of goods between ports in the United States and of the world by means of steam, sailing or other vessels. E. M. Kenworthy, president; E. B. Kurtz, vice-president; W. L. Reed, second vice, and W. T. Schutt, secretary.

MARINE ENGINEERING AND SHIPPING AGE is a member of the Associated Business Papers, Inc. (A. B. P.), National Association of Periodical Publishers, Inc., New York Business Publishers' Association and the Audit Bureau of Circulation (A. B. C.).

Requests for change of address should reach us two weeks before the date of the issue with which it is to go into effect. It is difficult, and often impossible, to supply back numbers to replace those undelivered through failure to send advance notice. In sending us change of address, please be sure to send us your old address as well as the new one.

Is Co-operation the Solution?

ACCORDING to Mr. James A. Farrell, president of the United States Steel Corporation, in his address before the recent Foreign Trade Convention at New Orleans, the solution of our shipping problem, and the shipping situation of the world as well, lies in co-operation. He would have the Shipping Board say to American companies: Co-operate with the foreign lines now competing with you; furnish one-half of the tonnage required to move the freight over a particular route; each to act as loading and discharging agent for the other; each to plan which ships of the two companies will operate on an alternate schedule and thus receive an equal portion of the business moving in both directions. In brief, replace unbusinesslike competition with sound co-operative operations; which will substitute profits for losses and will demonstrate to the American investor the advantage of owning shares in American ships, particularly at the low market prices prevailing today. The Shipping Board to sell to the American company the ships required for his share, and to sell to the foreign company such ships as may be required for his share. The price of the ships to be the same to each."

At first reading, one is apt to doubt the possibility of interesting, say, well-established British shipping companies in any such proposition but taking into consideration the

fact that the depression in shipping is world wide, that all maritime countries are confronted with problems similar to our own, due to overbuilding and the high prices paid for tonnage after the war, the advantages of an international regulation of the number of ships in the various trades are certainly worth considering.

No matter how strong financially a foreign shipping line might be, if it were confronted with the proposition of co-operating with a privately operated line or the alternative of competing with a Government-owned line having the Treasury behind it, there certainly would be a great incentive to take the course that would lead to adequate freight rates and a solution of the surplus tonnage problem through the co-operative method. If this is not so, why have pooling and rate conferences been so successful?

We are not in such a poor position to open negotiations for a co-operative plan as a good many people would naturally believe. It is true that our overseas commerce in privately-owned American ships is practically nil but, including our Government-owned ships, it has not so far to go to reach the coveted 50 percent of our foreign trade. This means that we have far more freight vessels than we can possibly use while, on the other hand, foreign maritime countries must sooner or later replace their obsolete vessels with modern ships.

To replace their vessels by new construction, as Mr. Farrell points out, would cost in the neighborhood of \$50 a deadweight ton in England while it would be good business for us to remove the menace that these vessels are to the shipping of the entire world by selling them at \$30 a deadweight ton. If a foreign line is willing to co-operate, let it enjoy the privilege of purchasing such ships from us as it may need on equal terms with American companies.

Now foreign shipping executives may not realize that America is determined to establish an adequate merchant marine of its own, even if it had to do so under the undesirable system of direct Government operation. They may not realize that since the defeat of the subsidy bill the tendency of Congress is distinctly toward discriminatory policies which, whether successful in their object or not, would certainly cause a great deal of damage to foreign lines. But they must realize that if a system of co-operation between American railways and American shipping is put into effect it would have a great influence on the amount of business that foreign lines could obtain.

Such a co-ordination may be forced at any moment, for the Merchant Marine Act of 1920 provides that unless the Shipping Board is convinced that there are not sufficient

American ships to take care of our commerce and so certifies to the Interstate Commerce Commission that the railroads cannot grant export rates to any but American ships.

How much better it would be if an amicable understanding could be reached with our maritime rivals on the basis of a fifty-fifty division of the direct trade. It would promote friendly relations and new business. It would secure stable and adequate rates for shipping without destroying competition in service and it would make work for the shipyards in reconditioning steamers and also in converting a goodly number of vessels to motorships.

A Reflex of the Defeat of the Ship Subsidy Bill

"A MERICAN bid for the world's carrying trade, about which so much was heard a couple of years ago, need not be seriously regarded."

The quotation is from an article in the Shanghai (China) Sunday *Times* of April 1 by its special trade correspondent at London, headed "Great Britain's Lead in New Ship Construction."

While at no time was it likely that the United States would ever take from England "the world's carrying trade," it is true that there *was* a chance to control a considerable part of its own cargoes, both outgoing and incoming. That hope, however, faded with the defeat of the ship subsidy legislation through a plot within the senate equally dastardly, in its way, to the one which nearly succeeded in a vote in favor of Nicaragua instead of Panama as the route for the Isthmian Canal.

In the same article the correspondent says: "I learn from reports received from the Clyde that new orders are exceeding the amount of gross tonnage launched and it is significant that the present is usually the dead season of the year in shipbuilding yards. Similar reports come from the Mersey and Tyneside." This is augmented by figures compiled by the Chamber of Shipping of Great Britain which show that on April 1, 1923, the idle tonnage of British merchant vessels was but 546,000 tons against 1,112,000 tons on July 1 of last year. Incidentally, the April 1 figure is the lowest since December, 1920, when the statistics were first collected.

In the Japan *Advertiser* of May 3 we read under the heading "Eleven Steamship Firms Get Subsidy" the fact that the Imperial Diet has voted three-year mail subsidies to 23 steamers operated by 11 different concerns; while from private sources comes the news that steps are being taken to improve the Pacific ocean steamship service of the Japanese lines between this country and the Orient. This may take some time but the policy is definite. Then, too, the Canadian Pacific Steamships, Ltd., is considering, if indeed it has not already decided upon, the routing of some of its fine *Empress* ships to Japan and China via the United States.

Since Congress will not again convene until December, and since the chances for the enactment then of legislation favorable to the American merchant marine are comparable to the odds in favor of the leopard changing his spots, it is distinctly up to the American shipbuilding and shipping in-

dustry to succeed in spite of the selfish acts of designing politicians.

MARINE ENGINEERING AND SHIPPING AGE has printed much about things which shall be done, if America is to take its proper place among the maritime nations of the world. From now on it will endeavor to so concentrate on its constructive program as to make the needs and ways and means clear at a glance. All of our efforts will be of no avail, however, without the hearty cooperation of all concerned. We refer not alone to the individuals and concerns who have to do with building and operating ships but also to the various organizations in the marine field, such as the Society of Naval Architects and Marine Engineers and American Marine Association.

It *can* be done. America as a nation has never yet failed in any undertaking of moment on which it has concentrated; and there is no reason why the shipping industry of the country should not by the same process remove the obstacles in its path. It *must* be done!

Does echo answer, "It *shall* be done?"

The Farmer's Interest in Shipping

THE farmers ought to be more concerned in the solution of our merchant marine problem than any other class of producers. It is important that the manufacturer who can regulate the creation of his products from day to day should have the facilities of sending his goods to foreign markets directly and promptly without transshipment, but it is far more necessary that the farmer whose potential wealth comes in harvests should be sure that he can place his grain on the market where he wants it and when he wants it there.

As pointed out by Mr. O. E. Bradfute, president of the American Farm Bureau Federation, at the eleventh annual meeting of the Chamber of Commerce of the United States, "the farmer pays the freight both ways. No matter whether that market be in Liverpool, in the case of wheat, or whether it be closer, the farmer pays the freight to the terminal or final market of his product." Taking the case of wheat grown in Kansas, he stated that the price obtainable for that wheat in Kansas in normal times was the price obtainable in Liverpool minus the cost of transportation of the wheat from Kansas to Liverpool. On the other hand, if the farmer buys an automobile the price is determined by the f.o.b. standard at the factory.

It is only natural, therefore, that the farmer should only consider the cost of transportation without considering whether or not the rates charged are sufficient to maintain a service that will always be at his disposal, no matter what conditions prevail in Europe. He quickly forgets the periods when tremendous sums of money were lost because foreign ships were withdrawn from our shores and concerns himself still less, if a foreign ship will take his wheat cheaper, with the reason why it is able to do so.

Far be it from our purpose to even suggest that the farmer should saddle the whole burden of the merchant marine. We do, however, want him to take an interest in shipping and to take part in the plans that must be made to formulate a

permanent policy upon which our merchant marine can be developed. If he does this, facts and findings upon which Congress will act can be devised but, if he remains aloof and fails to demand action from his representatives, then he more than any one else will be the principal sufferer, if ocean shipping reverts to the control of foreign lines who will fix the freight rates to suit no one but themselves.

Hull Surveyors' Pay

MARINE underwriters have been indulging in a discussion of the remuneration of their hull surveyors, and it develops that there is an uneasy impression among them that these important representatives are too often underpaid. With the larger insurance offices a staff of salaried surveyors is regularly maintained, but with the lesser lights it is the custom to employ unattached experts on a per diem or single inspection basis. It is the latter who are in a mood to rebel. They insist, and properly, that \$15 is scarcely adequate remuneration for a single inspection, especially when it is remembered that to prepare a man for such work a training of from five to ten years is absolutely necessary. The price is not invariably \$15, of course, but frequently it is no more. On the other hand, it is always much more than

that when the experts are employed by the assured or the repair yards—a field where only the very highest grade of talent is wanted. The underwriters' surveyor argues that his problems are intricate and of the first importance, and that he is brought into contact with the best minds in his line when he matches skill with the men hired by the assured and the repairers, whose interests are frequently directly opposed to those he represents. He complains that for work of the same grade as that for which he receives \$15 or \$25 his rivals are paid from \$50 to \$150; and the oddest thing about it is that these latter bills are in turn passed along to and paid by the same company of insurers that hands him out his lesser dole. When the matter is taken up with the underwriters the objection advanced to higher pay is that expenses must be kept down. A prominent underwriter, in an interview with one of our reporters, admits the propriety of the surveyors' complaint. He agrees that it is more than ever necessary at this time to keep marine insurance expenses down, but he feels that possibilities for saving do not lie in the direction of insufficient salaries for these very useful men. He feels that attention may well be paid to many of the items which enter into claims against underwriters, among them the fees allowed to the surveyors appointed on behalf of the assured but paid by the assurer.

Steamship Leviathan, the Largest Ship in the World, Entering the Commonwealth Dry Dock at South Boston, Mass.

The *Leviathan*, while in Boston, will have her bottom scraped and painted, her propeller shafts drawn and her steward supplies and other furnishings installed. On about June 15 she will start on a five-day trial trip to the neighborhood of Cuba with a party of several hundred distinguished guests on board. On this trip her picked crew and steward's department in particular will be given an opportunity to show their efficiency. On her return she will dock at New York where she will remain until July 4 when she will start on her maiden voyage as a premier passenger liner under the American flag to Cherbourg and Southampton.

E. P. Farley Appointed Chairman of Shipping Board

Definitely Decided to Adopt Direct Government Operation Unless Satisfactory Offers for Shipping Board Vessels Are Received

By Harold F. Lane*

ONCE more the United States Shipping Board is about to enter upon a new régime involving not only important changes in personnel, as the result of resignations, but also a probable change in its methods of operation, as it has been definitely decided to go to direct Government operation of the board's fleet unless satisfactory offers are received for its ships.

Albert D. Lasker, who has presided over the destinies of the Shipping Board as its chairman for the past two years, and who also led the administration's unsuccessful campaign for a ship subsidy bill, has resigned, effective on June 12, and the President on May 10 announced the appointment of Edward P. Farley, of Chicago, as his successor.

Commissioner Chamberlain has tendered his resignation to the President and will retire from the board some time in June and President J. B. Smull of the Emergency Fleet Corporation has announced his intention of leaving by July 1. Commissioner Thompson planned some time ago to quit upon the expiration of his term in June, but it is now expected that he will be reappointed and remain on the board.

Mr. Lasker's resignation, as well as that of Mr. Smull, is in accordance with the understanding had with the President. Mr. Lasker had promised to stay two years, which time expires on June 12. Mr. Smull had originally planned to return to private business on March 4 but then agreed to remain until Mr. Lasker resigned. Mr. Lasker plans to return to his advertising and other business affairs in Chicago. However, because the *Leviathan* was reconditioned under his régime, the Shipping Board unanimously adopted a resolution appointing him special representative in charge of her trial trip in June and also her initial voyage beginning on July 4 from New York to Cherbourg and Southampton.

THE NEW CHAIRMAN

Mr. Farley, the new chairman of the Shipping Board, is not a stranger to its affairs nor to the shipping business. He came to Washington in 1921 as vice-president of the Emergency Fleet Corporation in charge of liquidation and resigned to return to private business last August. Prior to his connection with the Fleet Corporation he had had 12 years of experience as a shipowner and in ship brokerage and marine insurance as president of the Edward P. Farley Company, of Chicago.

*Our Washington correspondent.

Mr. Farley was born in Madison, Wis., and was educated in private and public schools and at the University of Wisconsin. In 1909 he organized the Edward P. Farley Company and he was also later president of the Farley Navigation Company and the Waukua Transit Company, director of the Cornwall Terminal Company and secretary of the Glen Transportation Company. Since his resignation from the Fleet Corporation last August he has devoted his time to the affairs of the Lincoln Mills Paper Company, of which he was chairman of the board of directors. He is also a director of the Inderrieden Canning Company.

The announcement of his appointment from the White House said that the President and Mr. Farley had had numerous conferences, including an extended one on that day, and that he is in full accord with the policy previously announced by the Shipping Board and by the President for the maintenance of the American merchant marine. Chairman Lasker also said that Mr. Farley had played a part in the formulation of the policy of direct Government operation of the ships in case they could not be sold and that he had been in close touch with the board's affairs for several months.

The understanding that Mr. Farley would be the next chairman of the board was reached some time ago. He had been recommended not only by Mr. Lasker, but also by Walter C. Teagle, president of the Standard Oil Company of New Jersey who had been offered the chairmanship before Mr. Lasker was appointed and who has conferred with the President on Shipping

Board affairs on several occasions. Mr. Farley is fully informed as to the difficulties involved in trying to sell the Government's ships as he was in direct charge of the negotiations for ship sales while he was with the Fleet Corporation. In that connection he made a reputation for being a shrewd negotiator.

MO-4 AGREEMENTS TO BE SUPERSEDED

While the exact conditions under which the board will manage the fleet, if it is found necessary to go to direct Government operation, have not been announced, it is understood that the new chairman is fully in accord with the general opinion of the board that the new policy will not involve any arrangement between operators and the board similar to the present MO-4 agreements. The board has tolerated them in the hope that it would be able to sell the ships and

E. P. Farley, Who Will Succeed A. D. Lasker as Chairman of the Shipping Board

Ship and Sail on American Vessels by "Old Scotch"

DURING the controversy over shipping legislation last year, a very prominent American in a public speech said that if Americans would patronize their own ships with anything approaching the patriotic fervor given foreign ships by other nations, there would be but little need of Governmental help in this country. Considering that Americans are the greatest travelers in the world, and that more goods arrive and leave our ports annually than are handled by any other one nation, there is little doubt of the truth of his assertion.

Today, Americans can travel to almost all of the leading ports of the world in ships flying our own flag. Furthermore, for comfort, excellency of cuisine, and reasonableness of costs of transportation, it is difficult to excel these American lines. To arrive at the first hand knowledge of these assertions, the writer with his family recently made a trip on the *American Legion* to South American ports. This ship is one of the famous 535's owned by the Shipping Board and operated by the Munson lines on this important route. Other ships of the same type are operated to Europe and to the Orient.

The experience of the writer on this trip was so highly satisfactory and pleasing in every way, that a resumé of the principal features will, it is hoped, be of interest to people in the shipbuilding and marine field generally, and may possibly encourage some of them to make similar trips, and thus enjoy the fruits of their handiwork.

SOUTH AMERICAN TRAFFIC MOST IMPORTANT

The writer firmly believes that this particular line is one of the most important of the various routes operated by the Shipping Board, as it is to the great continent to the south of us that we must look for a large expansion of our

foreign trade. Splendid results in increasing the sale of our goods have already been accomplished, but still greater can and should be developed.

Four steamers are operated to South America, namely the *Pan-American*, *American Legion*, *Southern Cross* and *Western World*. It will be remembered that the construction of these 535's was commenced originally with the idea of safely transporting our troops to and from the great battle fields in Europe. As the armistice intervened before any of them were completed, those which had been advanced in construction were converted into combined freight and passenger ships for commercial purposes. They still possess the predominant features of efficient transports, and, as such, are a splendid asset for purposes of national defense. Their speed of 18 knots and better was fixed to make them safe from submarine attack, and their general construction and bulkheading were designed to exceed the rules laid down by the London Conference on Safety at Sea. Hence there is no question but that they are the safest ships which carry passengers on the high seas at this time.

OUR SHIPS OFFER EVERY INDUCEMENT TO PASSENGER TRADE

These four ships in the South American trade from New York, make it possible to maintain easily fortnightly sailings from each terminus. A round-trip from sailing point to sailing point occupies almost exactly six weeks. The minimum rate to Buenos Aires and return is only \$425. Let it be understood that any minimum rate stateroom on these ships is good enough for the most particular traveler, as these large rooms, each provided with two very comfortable beds, not berths, and with the finest lighting and plumbing are comparable to the best rooms on foreign ships.

With the exception of nine days ashore at Buenos Aires, every cost for the entire six weeks is included in the minimum fare. Where could any one, in these days of high prices, spend a vacation at more reasonable terms? Excellent food, entertainment of all kinds, including "movies" every other night, splendid weather and all the delights of foreign travel are included for the delectation of the traveler, at a total cost of approximately \$75 per week. The "splendid weather" is no romance either, for officers of the line who have spent years on this route will testify that not more than three bad days in one trip are encountered in an entire year. Hence the discomforts of sea travel are almost entirely eliminated.

FAIR WEATHER ROUTE

This trip might well be called the "fair weather route," as it is out of the vicinity of all periodic storms, and traverses that portion of the Atlantic where delightfully cool trade winds are the rule rather than the exception. In the coldest part of our northern winters, and within 36 hours from New York, these ships get into balmy weather, where the sea is never rough and sunshiny days follow one another. In the equatorial regions a few tropical showers lend interest rather than discomfort from what would otherwise be a monotonous series of perfect days at sea.

KING NEPTUNE'S GREETING

Crossing the line is of the greatest interest both prospectively and retrospectively. King Neptune welcomes all Americans who have never before been in his domains. The experience of being initiated into his kingdom is one long to be remembered with most pleasant recollections of the ludicrous incidents of the obeisances paid to His Majesty of the Deep. Each neophyte is furnished with a handsomely engraved certificate of citizenship, after he has gone through the ordeals of naturalization. Hardly has the traveler recovered from the delights of Neptune's visit, the Neptune ball and the Captain's dinner, before he is on the tiptoe of expectation of seeing his first South American port, "Rio in the morning at daylight" is the theme as he turns in on the evening of the twelfth day out from New York. The anticipation of seeing the world's most beautiful harbor is something to cheer up the most blasé and otherwise experienced traveler.

A SCENE OF INDESCRIBABLE BEAUTY

It is not my forte to describe adequately the sensation of getting up just as the sun is rising out of the Atlantic and beholding directly ahead of the ship, the fantastic array of beautiful mountains arising right at the shore line, the white lines of surf pounding at their very bases, and leaping many feet up their granite sides in impotent fury in the age-old battle between sea and land; of the magnificent tropical foliage covering the mountains to their very peaks; of the wonderful panorama of the harbor as you steam slowly through the narrow entrance, guarded on each side by frowning forts; of the beautiful and artistically colored houses and public buildings built on the level portion of the city and up the sides of the mountains; of the navy yard and ships of the Brazilian Navy, the many ships of all nations, and queer looking harbor craft darting in and out at this early hour of the morning. All these must be actually seen, as no amount of description can do justice to this wonderful seaport.

"Rio de Janeiro at last" you say to your neighbor, for heretofore during the passage up the harbor, you are too awe-stricken with the grandeur of the sight to waste time in conversation. The great white ship anchors in the harbor, is surrounded by small craft, the quarantine officer comes alongside, and within an hour you are warped in alongside of a splendid stone quay and begin preparations for going ashore. Your first impression will be the solidity and clean-

liness of the docks and their approaches. No slums surround them as in many of our seaports, and within a minute's ride you are on the leading street of the city, the splendid Avenida del Branco, the Broadway of Rio.

A whirl of sight-seeing around the many places of interest in this delightful city, and at midnight we are off again, viewing the harbor and brilliantly lighted city, under the spell of a moonlit tropical night. Nothing could be more enchanting.

THE SOUTHERN CROSS

To those of us who had never before sailed in the Southern Hemisphere, the gradual sinking of the Polar Star below the horizon, and the eventual disappearance of our old friend the Dipper from the northern skies were of great interest. Their temporary absence from our night gazing was in a manner compensated for by the steady rise of that brilliant constellation, the Southern Cross, famed in prose and poetry.

A comparatively short run of 1,020 miles brings us to the southernmost point of our journey and again at daylight we approach the harbor of Montevideo, the capital of that fine little republic of Uruguay, the traditional friend of Uncle Sam. Soon we are moored alongside a splendid stone quay, and our cargo of automobiles and other manufactured articles consigned to that port is being rapidly unloaded by the very efficient methods in use at these South American ports.

THE RIO DE LA PLATA

The Rio de la Plata which empties into the Atlantic at this port, means literally the River of Silver. It might better be named the Rio de la Mud, from its earthy appearance as it drains a huge area of South America's most fertile soil, and the constant erosion of the soil keeps the water rolled off its mouth for many miles out to sea. It is so broad that the eye cannot reach the other side, even from the channel, which is buoyed for almost the entire distance to Buenos Aires.

Having taken in the many sights of Montevideo, including the several seashore resorts in its vicinity, we leave again at midnight, and retire with our expectations agog with vision of seeing the great metropolis of South America in the morning, as it is only 115 miles away.

At nine in the morning we are abreast of the lower part of Buenos Aires with two tugs at our bow and two at our stern, to insure that we do not go aground in the narrow channel, this being in accordance with Government regulations for vessels of over 10,000 tons. As a matter of fact our keel frequently drags in the mud, because of the shallowness of the water, which must be frequently dredged to keep it navigable. The usual bright weather enables us to get a splendid view of this remarkable city, and its really enormous docking facilities, built in a series of basins along the entire waterfront of the city.

We enter the Darsens Norte where most of the liners dock and are rapidly placed alongside the dock by tugs that are handled most skillfully by expert boatmen. Of the many fine tugs and other craft, it is our first impression that all are of European build, the efficient American tug being conspicuous by its absence. Let our shipbuilders take note of this field for their activities.

All incoming passenger liners land at this same wharf where the Custom House is located, which tends to expedite our entry into the city, although if there was anything in our trunks which was not scrutinized by the vigilant Argentine Customs inspectors, we failed to notice it.

ARGENTINA IS A MECCA FOR SHIPPING

La Belle Argentine, whom all the nations of the world are wooing is a most wonderful country. With its unsurpassed natural resources, its almost entire absence of man-

manufacturing plants, its boundless quantities of foodstuffs for a hungry world, it is indeed a Mecca for the ships of all nations. If you would sell to these people, you must buy of their products, and without your own ships you will do neither. Prior to the establishment of the Shipping Board lines to this great South American nation our trade was negligible, notwithstanding that this should have been one of our principal trading places, both from geographical location and a spirit of friendliness engendered by the common interests of our peoples. Now with our own carriers we can enter into this great market with some chance of success, and woe betide our commercial interests if the present American lines are ever abandoned.

Before we had the Munson Line of Government-owned ships, the motor industry for example was practically controlled by Europeans. Now the tide has changed because

© Kadel & Herbert, N. Y.

Harbor of Rio de Janeiro

of the quick deliveries and low freight rates on American cars. Hence we rode to our hotel in an American taxi, and were much pleased to note that the majority of the motors seen on the streets are of well-known American makes, the omnipresent "flivver" type being in abundance.

WORLD MARKET FOR ARGENTINE'S PRODUCTS

North Americans are welcomed everywhere by the genial, sport-loving and happy people; happy because no Volstead act disturbs their dreams, as they sit at the tables in their sidewalk cafés and partake leisurely of their mild stimulants, of which black coffee forms a substantial part. Why should they worry? The world must have their fat cattle which find so easy a living on their fertile plains, their countless bushels of grain which grows so abundantly, the linseed of which they furnish one-third of the world's supply, the quebracho which tans the hides of which they can furnish unending quantities, and the delicious fruits which their orchards and vineyards produce, while the northern countries are covered with snow.

SHIPS HOLD THE KEY TO THIS GREAT STOREHOUSE

No rail routes can bring these products to the markets of the world, nor bring back manufactured articles to pay for them. Ships are the keys to unlock this great southern storehouse, and ships we must have and maintain, if we are to get from our South American brethren our share of their trade. A visit to the hinterland of this great metropolis is one long to be remembered. Fine railroads (under European management) traverse the country. As mile after mile is covered the eye is delighted with the rolling fertile acres, dotted everywhere as far as the eye can reach with herds of

the sleekest and fattest cattle browsing on the luscious alfalfa of which they have four crops every year without any care or attention. One story stone or brick estancias, fitted up with every comfort for the fortunate cattle owners dot the landscape. There are no barns or unsightly wooden fences visible. Fences many, but of concrete posts and substantial wire construction. Everywhere a well-kept appearance, with no signs of poverty. Oh! happy land, far from Bolshevism and Soviets, "farm blocs" and other evidences of social unrest.

Nine blithesome days are given the traveler in Buenos Aires, amid the attractions of beautiful parks, a wonderful race track, first class hotels and cafés with the best of food and drink, taxi rides so cheap that one cannot afford to walk, a never-ending number of points of interest, until your money is nearly exhausted and then you set sail again for far off New York.

THE SAILING DAY A BIG EVENT

Sailing day of a large liner from this port is of more than passing interest. The nationals of the many countries who reside there gather along the water front to see their home vessel sail away with friends and acquaintances, amid the stirring music of bands afloat and ashore, hundreds of streamers of vari-colored paper ribbons reaching from ship to wharf, the cheering of the crowds, the waving of fond adieus as the ship majestically steams out of the basin into the broad reaches of the river. Slowly the magic city fades from view and thoughts are centered on the long voyage ahead of us.

The next morning we are again at Montevideo, where great quantities of jerked beef and other products of the country are loaded by the busy winches. A peculiarity of trade is that the jerked beef is destined for Cuba, and opportunity is taken to ship it on these fast American vessels, in order that it may not be subjected to a long siege of tropical heat as would be encountered on the slower freight vessels. It is transhipped in New York for Havana, and reaches its destination by this circuitous route in better condition and quicker than it would by other and slower means of transportation.

LOADING COFFEE AT SANTOS

After visiting places in Montevideo which had been overlooked on the first visit, we leave that busy port in the early evening, and soon the ship's bow is headed northward up the coast. On the home voyage all of these American ships stop at the busy port of Santos, the seaport of Sao Paulo, which is located in the hills about 50 miles from the sea. Santos is approached from the rear, by steaming up a narrow river about five miles. It is said that out of this port is shipped two-thirds of the entire supply of coffee in the world.

Here again are splendid stone quays, with the most efficient loading apparatus imaginable. The coffee is loaded from storehouses hundred of yards away from the ship by an endless belt, and comes aboard in sacks so silently that one would not know the ship was being loaded. Bags of this staple breakfast necessity follow in an endless procession at the rate of nearly one per second. Three or four bronzed stevedores seem sufficient to have it properly stowed in the capacious holds of the ship. Some 20,000 bags were loaded in five or six hours after the stream was started.

A MANUFACTURING CENTER

In the meantime many passengers visit the delightful city of Sao Paulo up in the hills, where the air is cool and bracing. This beautiful place seems destined to be the principal city of Brazil. Not only is it the coffee center of the country, but it is rapidly assuming prominence as a manufacturing center, where really excellent shoes are turned out in great quantities. Other passengers who have not taken this ride up in the hills, have found amusement and recrea-

tion in visiting several nearby bathing beaches. All are aboard and ready to sail at 11 o'clock in the evening.

After one of the very few warm nights at sea we are again at the entrance of the world's most beautiful harbor, Rio de Janeiro, and are ashore by noon. More sight-seeing, shopping, visiting friends, dining at some of the fine hotels, visiting the exposition, etc., occupy our time for the 24 hours' sojourn in this Paradise of the South.

At exactly noon on the following day amid similar scenes of farewell as those at Buenos Aires, we leave the hospitable shores of South America for the long homeward bound trip. Every stateroom is filled, showing that American ships are still popular despite their dry reputation. As one Briton expressed it, "Better to have flowing water in the baths, than flowing stimulants at the bar."

SOUTH AMERICANS PATRONIZE OUR SHIPS

Over one-third of the passenger lists are South Americans who mingle with their North American brethren on terms of the greatest amity and friendship. By the third day out incipient outbreaks of English-Spanish and Spanish-English are heard, and it is conceivable that if the voyage had lasted for a couple of months all would have been conversing in both English and Spanish in an understandable manner. Dances every evening, shuffle board, deck quoits and tennis, walking matches, boxing bouts, and horse-racing help to wile away the time, so that each passenger seemed to regret the passage of every day instead of being afflicted with ennui.

THE GAME OF HORSE-RACING

This horse-racing at sea is indeed a novelty and enjoyed by nearly all. Courses of various lengths are laid out on deck, and miniature horses each numbered from 1 to 6 respectively, champ at their bits ready to move a portion of the course, as their numbers are thrown on the dice rolled by volunteers from the passengers. Sometimes the numbers are called out in English and sometimes in Spanish, but all who had bet the munificent sum of 25 cents on their favorite horse could understand "cinco" and "five" or any other numeral up to six. Exciting finishes frequently occurred causing volumes of cheers which must have surprised the flying-fish in the vicinity.

The Dipper once again resumes its place in the firmament, shortly to be followed by the reappearance of Polaris, while the Southern Cross gradually passed from view as the steady 17½ knot pace of the good ship ate up the degrees of latitude on our northwesterly course. Clear skies, indigo waters ruffled by cooling trade winds featured every day, and we were before long approaching the latitude of the Bermudas, which on the tenth day out from Rio, were passed, plainly in view, about 9 miles off.

In the latitude of Hatteras on the following day, we awoke to find the ship rolling violently and running with a screeching southeast gale, which at times assumed a velocity of 50 miles per hour. Any one who doubts the seaworthiness of these 535's should have seen this ship in action. Aside from an occasional swish of spray, the decks fore and aft are dry. It is doubtful if a single soul on the ship was seasick, as all by this time had on their "sealegs," and the blow was a delightful change after the monotony of fine weather.

THE END OF A DELIGHTFUL TRIP

Turning in Sunday night, with the hoarse whistle sounding warnings in a dense fog and rain, we awoke at three the following morning, and found the ship serenely anchored off Quarantine at Staten Island, with a bright moon shining in a cloudless sky. We also awoke to the cold realization that the most delightful trip of our experience had ended, and that we must resume the monotonous existence of wrestling for a living.

The trip up the harbor was a delight to our Argentinian

shipmates, who eagerly searched for the Statue of Liberty, the Woolworth Building, the Battery, Broadway, but of all things those most wonderful skyscrapers of which they had read and dreamed for many months.

By the inquisition of our benevolent Government in the shape of numerous quarantine, immigration and customs officials, and we are once more in the Land of the Free, our first inquiry being "have they settled on a Shipping Policy yet?"

Whatever is done for shipping, we all unite in praying that the South American lines must be kept up and continually expanded.

E. P. Farley Appointed Chairman of Shipping Board

(Continued from page 324)

with the idea of keeping in business operators who might become purchasers, if conditions for operation on their own account were made more favorable by the adoption of the subsidy plan. It has been understood for some time that direct Government operation probably would involve the employment directly by the board of ship crews and officers and the payment of brokerage fees to ship brokerage firms for cargoes obtained for the Government vessels. It has also been the idea that a number of the present managing operators would be used as brokers, as many of them were formerly engaged in that business.

Extension of the coastwise laws to the Philippines will not be seriously considered until the question of whether or not there is to be direct Government operation has been definitely determined, but, if the Government remains in the shipping business, it would expect to be a favored carrier in that service.

BIDS ASKED FOR SHIPS

Bids for the Government's passenger and cargo ships were to be received up to May 28, according to a call issued by the board on April 28. Bidders were requested to enter into an agreement to maintain line service on one or more of 18 routes named by the board, or such other routes, acceptable to the board, as might be proposed by the bidder.

The proposed 18 services which were published in our May issue were suggested for the purpose of eliminating overlapping or duplication and also so that each service would include a reasonably wide range at each terminus, thus affording larger markets from and to which to take cargo. The board, however, will consider any service proposed, if the bidder will guarantee to operate for a specific period over the routes selected by him. Further, the board will agree upon the acceptance of any tender not to operate Government owned ships in competition with him while adequate service is maintained.

RECONDITIONING CONTRACT APPROVED

President Harding on May 8 approved the action of the Shipping Board in awarding the contract for the reconditioning of the *President Buchanan* to the Newport News Shipbuilding and Drydock Company instead of to the Brooklyn navy yard, in spite of protests made by the Brooklyn Chamber of Commerce, the navy yard and the American Federation of Labor. The President acted after requesting a report from the Shipping Board, which showed that the navy yard had not submitted a firm bid but only an estimate and that if the cost exceeded the estimate the board would have to pay the additional cost. It was also pointed out that if the *Leviathan* reconditioning job had been made on the basis of a navy yard estimate the cost would now be about \$1,200,000 higher than it was because the Newport News company had found its costs to be about 15 percent higher than its bid.

Passenger and Freight Steamship Alleghany

New Coastwise Steamships Alleghany and Berkshire

**Passenger and Freight Vessels for the Merchants and Miners
Transportation Company Combine Comforts and Conveniences
of Ocean Liners with Efficient Cargo Handling Arrangements**

ONE concrete illustration of a happy combination of efficiency and economy is to be found in the new steamships recently completed by the Federal Shipbuilding Company, Kearny, N. J., for the Merchants and Miners Transportation Company of Baltimore. One of these vessels, the *Alleghany*, is now in service between Baltimore and Jacksonville, via Savannah, and the other, the *Berkshire*, will trade between Philadelphia and Jacksonville, via Savannah.

As might be expected from a steamship company that has been established since 1854, efficiency has been the prime object in the construction, equipment and appliances of these vessels. The passenger accommodations have been studied from the standpoint of comfort, convenience and cleanliness rather than lavish adornment. All the latest devices for insuring the safety of life at sea have been adopted. The question of quick despatch in loading and discharging cargo has been solved by the installation of labor-saving appliances for handling freight, including bulky automobiles of all types.

PRINCIPAL DIMENSIONS

The principal characteristics of the *Alleghany* and her sister ship, the *Berkshire*, are as follows:

Length overall	368 feet 0 inches
Length between perpendiculars	350 feet 0 inches
Beam, molded	52 feet 0 inches
Depth to main deck	27 feet 3 inches
Depth to hurricane deck	35 feet 0 inches

These steamships have steel hulls, single screws and are what is called the "hurricane deck" type of combination passenger and freight vessels. They have straight stems,

elliptical sterns and are schooner rigged with two steel pole masts. There are four steel and two wood decks with a steel deck house on the hurricane deck and wood deck houses on the promenade and boat decks.

CONSTRUCTED ON THE ISHERWOOD SYSTEM

The hulls are built on the Isherwood system of ship construction with scantlings, workmanship and material in accordance with American Bureau of Shipping class + A 1 E. The stem is a rolled steel bar having a scarp at the lower end; the stern frame is a wrought iron forging constructed in two pieces with suitably located scarps and with the rudder and propeller posts extending into the hull to give good connections to the floors.

The rudder is of the single plate type, built up, with a wrought iron post and wrought iron arms opposite each pintle. The pintles are of steel having brass casings and working in lignum-vitæ bushings in solid forged gudgeons. The weight of the rudder is supported on a cast iron bearing, lined with white metal and fitted with a brass bearing ring and a cast iron supporting collar made in halves.

STRUCTURAL DETAILS

As may be seen from the drawings accompanying this article, the double bottom extends from the fore peak bulkhead to the after peak bulkhead. The center vertical keel which divides the inner bottom fore and aft is 43 inches deep. One intercostal longitudinal girder is placed on each side of the center vertical keel but in the way of the engine room and in the forward end of the vessel, additional intercostals are fitted.

The framing consists of channels running fore and aft

Plan of Main Deck of S. S. Alleghany

on the Isherwood system and reinforced by transverse belt frames. The boat and promenade decks are supported by transverse deck beams but the four structural steel decks are framed with bulb angle deck longitudinals supported at widely spaced intervals by transverse beams in accordance with the regular Isherwood design. One row of widely spaced tubular pillars is fitted under the orlop, lower, main and hurricane decks. Special pillaring is constructed under masts, winches, windlass and steering gear.

BULKHEADS

Six bulkheads subdivide the vessel into watertight compartments. Four of these bulkheads extend to the lower deck while the forward and after peak bulkheads extend to the main deck. A watertight door, operated far above the waterline, is fitted in the after engine room bulkhead for access to the shaft alley. A strong steel dust-proof non-watertight bulkhead with a door is fitted between the engine and boiler rooms.

ACCOMMODATIONS

The boat deck, which is constructed of $1\frac{1}{8}$ -inch tongued-and-grooved white pine and covered with canvas is laid on yellow pine carlins and is carried to the vessel's side forming the top of the promenade deck. The pilot house is located on the forward end of this deck on a raised platform which extends to the ship's side, forming the bridge. The top of the pilot house extends 24 inches above the boat deck house providing for an unobstructed view aft through plate glass windows. The forward end of this house is well rounded having closely spaced windows with fixed lower sashes of $3/16$ -inch plate glass in oak frames. The upper sashes are of the sliding balanced type.

The pilot house is heated by a brass pipe coil around the forward end. All hardware and appliances in this room are of brass.

Among the instruments installed in the pilot house are a McNab direction and revolution indicator which shows exactly what the engine is doing, a Lord Kelvin compensating binnacle with a 10-inch card and compass, a double faced repeating telegraph, 12 inches in diameter, a loud-speaking telephone to the engine room, the usual whistle pull and an automatic control for the whistle, tell-tales for masthead, running and stern lights, the operating equipment for a submarine signal apparatus, an alarm board from the pneumatic tube, electrical indicating fire alarm system installed throughout the staterooms, a smoke indicating system which reveals the slightest fire in the cargo holds, the usual barometers, thermometers, clocks, night glasses, megaphones, etc.

Passing to the life-saving apparatus on this deck, there are seven metallic lifeboats, each capable of carrying 42 persons and one motor boat having a capacity for 33 people. Eight Jacob's ladders having a length equal to the distance of the boat deck above the light water line are stowed on this deck.

The officers' quarters are located on the boat deck. They are finished in white and paneled with Vehisote. Each room is fitted with a white pine paneled door and with a brass wire Venetian screen door. The captain and chief engineer are each provided with a double bed and the remaining officers with metal berths of the wall type.

PROMENADE DECK HOUSE

The promenade deck house is constructed of wood and contains in addition to the staterooms, public toilets, etc., a music room, a smoking room and a social hall. The sills, posts and stanchions are of yellow pine. The outside is paneled with $1\frac{1}{8}$ -inch white pine and inside with 1-inch white pine sheathed with Vehisote. All weather doors are of white pine with oak Venetian brass wire screen doors inside.

The music room has double entrance doors, including screen doors fitted on each side, furnished in cane mahogany with tapestry upholstery. An artistic circular skylight located over the main stairway is finished in harmony with the interior work.

This room is carpeted and furnished with a piano, comfortable chairs, sofas and tables.

Aft of the music room is the smoking room. This is a very pretty room finished in cherry strained mahogany with a paneled ceiling. The floor is laid with rubber tiling fitted in large squares. Double entrance doors open on each side to the promenade deck and access is also provided to the quarters fore and aft. This room is furnished in mahogany with leather upholstery.

On the after end of the promenade deck is a social hall with a circular skylight finished to suit the interior. A striking feature in all the public rooms on this deck is the drinking fountains fitted with spring cocks which supply cold running drinking water. The social hall is furnished with reed furniture with tapestry upholstery.

The hurricane deck house is constructed of steel and contains, in addition to the staterooms, the dining saloon, pantry and a lounge furnished in mahogany with tapestry upholstery. The dining saloon has a seating capacity for 107 persons at tables arranged to seat 2, 4, 5 and 6 people. Mahogany tables with hinged storm guards and mahogany chairs, upholstered in hair and leather, together with two large mahogany buffets having large beveled edge mirrors give this public room a cheerful and rich appearance. The floor is laid with Lit-o-Sil-o and covered with Beaver Tile.

At the forward end of this deck is the lounge ex-

tending the full width of the house. A large hardwood stair-
way, fan-shaped at the bottom leads to the music room above.

STATEROOMS

Four staterooms at the forward end of the hurricane deck
house and six at the forward end of the promenade deck
house are fitted with double metal bedsteads and with a
single metal berth above. There are also 41 two-berth and 8
one-berth staterooms in the hurricane deck house and 40 two-
berth and 6 one-berth staterooms in the promenade deck
house.

Every stateroom is furnished with a washstand fitted with
running hot and cold water. Nothing has been overlooked to
make these rooms exceptionally comfortable in every respect,
even to providing berth lights similar to those used in Pull-
man sleeping cars so that one can read easily in bed.

PLUMBING

On the promenade deck there are three bathrooms fitted
with porcelain tubs and six shower rooms connecting to
staterooms and on the hurricane deck 10 shower rooms con-
necting to staterooms. Running fresh and sea water is sup-
plied to all baths and the showers are provided with a spe-
cial thermostat valve which prevents any possibility of any-

one accidentally scalding himself. Mosaic tile is laid on the
floor over sheet lead and in the way of showers up the sides.
Elsewhere the walls are covered with Vehisote tiling treated
with waterproof enamel.

SALOON PANTRY

The pantry is located just forward of the dining saloon
on the port side. Access is provided by double doors direct
from the saloon. The floor is laid with mosaic tiling and the
walls are covered with Vehisote tiling. Included in the
equipment are the following: A seamless cast iron Vortex
dishwashing machine, a battery of 5-gallon heavy nickel-
plated copper coffee urns, a combination urn stand, cup
warmer and drainer, a three-bucket egg turner and cooker,
a nickel silver top steam table, 9 feet 6 inches by 30 inches,
an automatic bread toaster and an 18-inch by 36-inch elec-
tric griddle.

GALLEY

The galley is located on the main deck almost directly
below the pantry. The floor is laid with brick efficiently
drained and the ceiling insulated with mineral wool and
galvanized sheet steel. The equipment here consists of a
steel plate galley range containing three fires and four ovens,

Social Hall

Dining Room

Lounge

Smoking Room

an upright vegetable steamer, a 25-gallon aluminum double jacketed steam stock and soup kettle, a 16-inch vegetable peeler with carborundum-lined body and revolving disk, a steam press or warmer and a coke bake oven having a capacity of 60 one-pound loaves of bread.

An exhaust system of ventilation is provided for the state-rooms, public spaces, pantry, galley and public toilets. Telephones are installed in each room.

CARGO PORTS

For quick and efficient loading and discharge of freight the ship is provided with 3 watertight cargo ports on each side of the main deck. These ports are 10 feet by 6 feet 7 inches in the clear. On the lower deck there are five watertight cargo ports ranging from 9 feet by 8 feet to 10 feet by 7 feet in the clear. These ports when opened are suspended by chains from trolleys running on a flat bar rail at the gunwale. One lumber port about 4 feet by 3 feet 6 inches is also fitted on each side of the vessel just aft of the forward peak bulkhead.

It may be said at this point that the principal revenue of this line comes from the carriage of freight and that every effort has been made to expedite its handling. The character of the freight is such that it cannot be safely stowed for great depths without damaging the underneath portions, so our complete steel decks have been fitted. The five hatches are served by jib cranes and winches, two being located at each hatch.

PROPELLING MACHINERY

The main propelling machinery consists of four single ended, return-tube Scotch boilers fitted with the Todd oil burning system and Howden forced draft and one 4-cylinder direct acting triple expansion engine of the Hooven-Owens-

Music Room

entschler type. The propeller is of the built-up class having four right handed blades.

Complete information relating to the auxiliary machinery is tabulated on the data sheet accompanying this article, but there are several points on which comment can be made. The pumps which were supplied by the Warren Steam Pump Company, with the exception of the fuel oil feed pumps, have their pump cylinders of Government bronze. The fuel oil pump cylinders are of iron. All the vertical pumps have piston rods of the divided type; that is, the steam end of the piston rod is of Tobin bronze. These rods are joined by heavy crossheads and caps of forged steel. The main air pump has two steam and two air cylinders and the cylinder connections are so arranged that in case either steam

cylinder becomes disabled it can be cut off and the pump run on the opposite cylinder.

ECONOMICAL SPEED

Referring to the horsepower of the engine and the speed of the ship, it has been ascertained that here again the principles of economy and efficiency have been coordinated to

Corner of Social Hall

the fullest extent. A higher speed could not have been obtained except at a sacrifice of cargo-carrying capacity through finer lines and increased weight and cost of machinery. As desirable as high speed may be in the usual passenger trades, in this case there is no advantage as the speed was determined so that the vessel would arrive at her terminal ports early in the morning, thus giving the stevedores a full day to load and discharge. As can easily be seen there would be no advantage in arriving at a port before daylight and it would be impossible to increase the speed sufficient to cut off 24 hours in her sailing time, which condition would be required in order to obtain the full day for the stevedores.

All in all these ships represent the latest and most modern type of vessels in the Atlantic coastwise trade, having comforts and conveniences for the passengers that are only found in the larger types of ocean liners. They are a splendid example of the kind of workmanship that can be turned out in an American shipyard and it is to be hoped that other steamship owners will give serious consideration to replacing such vessels as have become antique and which foreign ships would drive out of business if it were not for the coastwise laws. Owners may well consider the fact that when the *Alleghany* and *Berkshire* were contracted for the price of steel was only \$1.40 a hundred pounds. It is now \$2.50 with the prospect that not only steel but other materials and labor will be dearer in the future.

No Recovery for Injuries Unless Vessel Is Unseaworthy

WHERE an oil tank steamship is new and modern in design, with all necessary improvements to enable her to perform the service in which she was employed and there was no failure to supply proper appliances nor to keep them in order, there can be no recovery for maintenance, cure and wages and this has not been changed by the Seamen's Act, March 4, 1915, Sec. 20, declaring seamen having command not fellow servants with those under their authority, says the Court in the *Swiftsure*, 286 Federal Reporter, 689.

Mammoth Car Ferry Launched on Ohio River

Steamer Will Handle Complete Trains Consisting of Mogul Engine and Eleven Steel Pullmans at a Single Crossing

THE recent launching of the huge railroad car transfer steamer *George H. Walker* in the Ohio River attracted a large crowd of spectators, as the event marked history in marine construction for the inland rivers and waterways. This steamer is the largest and most modern boat that has ever been built and launched for the inland rivers and it will be placed in railroad car transfer service across the Mississippi River between Mexico and the Southwest, and New Orleans and the East. The river crossing is made between Anchorage, La., and Baton Rouge, La. Complete trains consisting of a powerful Mogul engine and 11 85-foot steel Pullman cars; or 25 loaded freight cars will be handled by the boat at a single crossing.

The steamer has a molded length of 340 feet; a beam over the guards of 91 feet 6 inches; a molded beam of 56 feet and a molded depth of 11 feet. It is of all steel construction throughout, carrying three tracks with switches arranged so that the cars can be shifted from any one track to the other two. The parallel midships body is about 244 feet long. The entrance is 48 feet long and of the modified scow-bow type, so as to improve the navigating characteristics and to sweep aside driftwood. The boat has a long sloping stern 48 feet in length.

HULL CONSTRUCTION

The hull is divided into 26 watertight and two oiltight compartments by means of 13 transverse bulkheads and a centerline bulkhead. In addition to the longitudinal bulkhead on the centerline, there is one non-watertight longitudinal wing bulkhead on each side in way of the side tracks. These wing bulkheads are intercostal between the transverse bulkheads. The three fore and aft bulkheads and the sides of the boat, forming five longitudinal girders, provide ample strength and rigidity under all conditions of loading. The scantlings are such as to withstand the weights superimposed and to absorb shocks and impacts resulting from the heavy locomotives passing from the land cradles on to the floating structure.

The shell plating is 7/16 inch throughout; deck plating 3/8 inch and 7/16 inch and all bulkheads are made up of 3/8 inch plating. The transverse bulkheads are closely spaced and with one longitudinal bulkhead in way of each track, the weights of the cars and the stresses resulting therefrom are well distributed over the entire structure. The racking and torsional strains are taken care of by trusses placed athwartship between the transverse bulkheads.

The guards are supported at every fourth frame by substantial outriggers of the truss construction type, and a deep web plate is fitted at every transverse bulkhead. In way of the machinery space, the outriggers are placed on alternate frames. Additional support is provided in the way of the paddle-wheels and boilers by means of stiffeners and hog rods from one side of the boat to the other.

The deck house is a comparatively light structure consisting of 1/4 inch plating at the bottom with 3/16 inch plating at the top and 3/16 inch flooring. Stiffeners are placed on alternate frames, with deck beams at every frame.

The three tracks are spanned from starboard to port side deck house by a bridge 27 feet long, supported by two heavy trusses and by double channel columns rising from the hull. The pilot house is built of wood and its dimensions are 16 feet by 18 feet.

The boiler plant is made up of two batteries of boilers, each consisting of two boilers 6 feet in diameter and 18 feet

long; one battery on the starboard and one on the port side of the boat. The boilers are of the modified Bonson type and will be adapted to the burning of fuel oil but will also permit of the possible use of coal. Oil burners are of the Lientz type, using steam for atomization.

These boilers are designed for 200 pounds pressure and have a total heating surface of 7,520 square feet. One battery of boilers is of sufficient capacity to furnish steam for both engines, so that the boilers on the other side of the boat can be shut down for repair or cleaning without suspending the operation of the boat. The flues are 3 1/2 inches in size and water pipes connecting the headers are 4 inches, outside diameter.

Induced draft is provided for by steam exhausting into the smoke stacks, but generally the boilers will be operated under natural draft and the steam exhaust will be used for heating the feed water. The steam lines and the feed water lines are interconnected so that the main engine and auxiliaries on one side can draw steam from the boilers on the opposite side and the boilers can be served by the auxiliaries on either side. The boilers are lagged with 2 1/2-inch "Sil-O-Cel" and the flame bed is built of fire brick and "Sil-O-Cel" and covered on the outside with sheet metal.

PROPELLING MACHINERY

The steamer is propelled by independently operated side wheels, 31 feet in diameter and 14 feet in length, having 18 buckets 36 inches wide. The wheels will be driven by two engines of the two-cylinder simple non-condensing type. The wheels are carried by three cast steel flanges mounted on the shaft, which tapers to 11 inches in diameter at the outboard end.

The cylinders of the engines are 18 inches in diameter with 36-inch stroke and are inclined at an angle of 15 degrees from the horizontal, forming an open inverted "V." Each engine develops about 600 indicated horsepower at 90 revolutions per minute when supplied with steam of 200 pounds pressure.

The cylinder and valve chest are cast integral of close grained cast iron, forming a rugged and simple engine. Valves are of cast iron of the piston type. The piston rods and connecting rods are of high-grade forged steel machined all over. All the valve rods and piston rods have metallic packing. The connecting rods, which are of the closed-end type, are fitted with semi-steel boxes and babbitt lining.

SINGLE REDUCTION GEARS USED

The valve gear is of the Joy type, especially designed for the service, by means of which a wide range of cut-off is obtained whereby the power can be nicely regulated to suit the requirements. The speed of the engine is geared down from 90 to 15 revolutions per minute at the wheel by means of a single set of spur gears. The cylinders and valve chests and all steam pipe are carefully lagged to insure dry steam in the operation of the engines.

All bearings are babbitt lined and well lubricated to effect a reduction of frictional loss to a minimum. All parts entering into the construction of the engines have been designed with a view to economy in operation and easy access for maintenance and overhauling.

The auxiliary equipment of the boat is complete in every respect. One 9 by 5 by 10-inch horizontal duplex Worthington feed pump is installed on each side of the boat. There is one 9 by 5 1/4 by 10-inch horizontal duplex Worthing-

Side and End Elevations of Mississippi River Car Ferry George H. Walker

Deck Plan of Railroad Car Ferry George H. Walker

on sea suction pump on the port side and one on the starboard side for transferring feed water from the river to the Michrone open type feed water heaters. These pumps can also be used for fire pumps. There is also installed a $4\frac{1}{2}$ by $2\frac{3}{4}$ by 4-inch sanitary pump of the horizontal duplex type. Four $4\frac{1}{2}$ by $2\frac{3}{4}$ by 4-inch horizontal duplex pumps are installed for fuel oil service. On each side of the boat there is a feed water storage tank 5 feet in diameter and 10 feet long. The feed water heaters are mounted on top of the storage tanks.

The steering engine is a two-cylinder simple engine—18 inches in diameter with a 7-inch stroke and is located aft between the two tillers. A screw direct connected to the crankshaft actuates two cross heads, one on each side, which move in athwartship direction, and are connected to the tillers by means of links of "H" beam section. The following gear is connected to the control valve whereby the angle of the rudder, as indicated by the tell-tale, can easily be controlled by the helmsman. The steering engine is operated from the pilot house by means of shafts and gears.

There are two balanced rudders of the composite type entirely covered with steel plates and filled with oak, the older stock being $11\frac{3}{4}$ inches outside diameter. There is installed on the boat a 10-kilowatt De Laval steam turbine generator, which provides current for the lighting of the boat and for the search lights.

Every provision has been made to safeguard the passengers through watertight sub-divisions of the hull and through ample life boat facilities. The fire equipment apparatus and life saving equipment are up to date in every respect and meet the requirements of the United States Steamboat Inspection Service. Mechanical davits of the "Steward" type are fitted for all life boats. The interests of the passengers on the cars have not been overlooked as the boat affords a 750-foot promenade during the period of crossing and an artistic hand rail is provided along the deck promenade.

The design and construction of the complete boat, including the boilers and the engines has been handled by the engineering staff and the shops and boat yards of The Dravo Contracting Company and launching was made at their Ohio River Boat Yard on Neville Island before a large audience including prominent guests representing the marine and river interests of the inland waterways, who were attracted because of the unique interest in this piece of river craft which has focused attention on marine construction in the Pittsburgh district.

The boat has been constructed for the Gulf Coast Lines, New Orleans, Texas & Mexico Railroad, with general offices at Houston, Texas, at a cost of approximately one-quarter of a million dollars. As the largest vessel of its type so far built, its performance will be watched with interest.

New Standard Oil Motor Tanker Standard Service

Trials of M. S. Standard Service Show Advantages of Diesel Electric Drive

SEA trials of the Standard Oil Company's first Diesel electric driven tanker *Standard Service* were completed off San Francisco on April 2 and have been pronounced eminently successful by both the builders and the owners.

The normal speed of the propeller is 130 revolutions per minute, but during the builders' trial it was operated at

about 145, and the load was less than 1,000 amperes, whereas the full load rating on the motors is 1,065 amperes.

During the owners' trial the craft was well loaded and the full load current was approximately 1,000 amperes with the propeller turning at 145 revolutions per minute.

Readings taken on four different occasions when the control was thrown from full speed ahead to full speed astern showed that at no time did the load go above 1,000 amperes. The change from full speed ahead to reverse took from ten to twelve seconds. During the reversal, all vibra-

Electrically Driven Deck Winches on Standard Oil Tanker Standard Service

Pilot House Control on M. S. Standard Service

ion was eliminated and unless one were observing the instruments he would have no indication of what was taking place on the propelling equipment. One of the directors of the Standard Oil Company, who was steering the boat with one hand and operating the controller with the other, was asked to throw the controller from full speed ahead to full speed astern and was amazed at both the simplicity and the perfect control.

The principal dimensions of the *Standard Service* are:

Length	210 feet
Beam, molded	40 feet
Depth	16 feet 6 inches
Block coefficient	0.76
Lean load draft	15 feet
Loaded displacement	2,725 tons
Deadweight	1,875 tons
Cargo-tank capacity	12,400 barrels
Cargo-hold capacity	225 tons
Fuel-tank capacity	585 barrels
Propelling motor power	600 brake horsepower
Estimated speed, loaded	9 knots
Fuel consumption, running	(24.5 barrels per 24 hours)
Cruising radius	24 days
Fuel consumption, pumping out	15 gals. per hr.
Pumping-out time	6 hours

The tanker is driven by propelling units consisting of two General Electric 300 horsepower motors mounted on the same base and with a common shaft driving a single propeller. Current is supplied by two General Electric 245 kilowatt, direct current generators with a 30 kilowatt exciter connected to each, each generator and exciter being direct connected to a 400 brake horsepower six cylinder four cycle Pacific-Werkspoor Diesel engine.

The main control equipment consists of a control panel in the engine room on which are installed the various switches, field rheostats, instruments, contactors and relays; a panel in the pilot house carrying instruments for indicating propeller speed, line amperes and motor field amperes;

a controlling rheostat for varying and reversing the shunt field current of the two generators; and a propeller speed magneto connected electrically to the speed indicators on the panels.

As the same generating sets which supply the motive power of the craft furnish power also for the cargo pump motors for discharging the cargo, no auxiliary plant is needed. The equipment is capable of discharging the entire cargo in about six hours. Sets of lubricating oil, cooling water, bilge and other pumps are driven by each engine. A storage battery and a small auxiliary generating set is furnished for supplying light when the vessel is not in operation.

Auxiliary Diesel Yacht Hussar

MESSRS. BURMEISTER & WAIN, LTD., Copenhagen, recently launched the seagoing steel auxiliary Diesel yacht *Hussar* for Edwin F. Hutton, of the New York Yacht Club, from designs by and under the supervision of Messrs. Cox & Stevens, of New York. The *Hussar* is built to the highest classification of Lloyd's with the following dimensions:

Length on deck	196 feet 7 inches
Length, waterline	164 feet
Breadth, molded	33 feet
Draft, mean	14 feet
Cruising radius	9,000 miles

She is provided with auxiliary propelling machinery of Burmeister & Wain's yacht type, developing 800 indicated horsepower, anticipating a speed without sails of 11.5 to 12 knots. The engine will drive a two-bladed reversible feathering-type bronze propeller, so designed that when the vessel is under sail the blades may be turned in such a way as to offer no interference to sailing, and at the same time completely fill the propeller apertures. The equipment of auxiliary machinery will consist of two 33-kilowatt Diesel-driven dynamos, and the electrical installation includes Edi-

Diesel Yacht Hussar Ready for Launching

son storage batteries of large capacity, electric boat hoists, equipment for handling sails by power, electric windlass, refrigerating machine of large capacity.

The forward and after overhangs are reasonably short and the stem of the clipper type. The rig is that of a three-masted schooner, having a yard on the foremast for long runs with favorable wind. In order not to exceed the limiting factor for operation in and around New York, the

height of the topmasts permit passing under the Brooklyn Bridge.

In order to meet the owner's intention to make extended voyages at sea, several features were decided upon, including a raised poop deck, allowing dry deck space for the owner and his guests, even in heavy weather. There are provided very comfortable quarters, no expense having been spared in any direction where either seaworthiness, strength, comfort or attractive appearance is concerned.

Another Luxurious Liner for the Italian Lloyd Sabaudo Fleet

DURING the first week in April trials were run in the Firth of Clyde of the Italian Lloyd Sabaudo liner *Conte Verde*, which has been built and engined by William Beardmore & Company, Ltd., of Dalmuir. A sister ship, the *Conte Rosso*, also built and engined by William

class passengers, and a crew of 420—making a total of 2,820.

The first class passengers are berthed in specially large cabins for one or two persons, while certain cabins can be made intercommunicating so as to form suites. Besides, there are a number of special suites, each comprising bedroom, dressing room and bathroom. The first class dining rooms are unique, as the space of three decks is utilized for an upper and a lower dining saloon, thus obtaining for each a headroom of 12 feet 6 inches. The first class public rooms, the designs of which were prepared by Italian architects, include the two dining saloons, a music room, a social hall, a library, and a smoking room with cafe. In addition a large deck area is set aside for recreation and promenade purposes.

The second class passengers have large four-berth cabins, a dining saloon, a lounge, and a smoking room, while the third class berthage is of the open type in large compartments, with appropriate dining and recreation spaces.

Italian Lloyd Sabaudo Liner *Conte Verde*, of 18,500 Gross Tons, Built and Engined by Messrs. William Beardmore & Company, Ltd., Dalmuir, Scotland

Beardmore & Company, has been giving very satisfactory service on the Mediterranean and North and South Atlantic routes. When completed she was regarded as the most sumptuously furnished and decorated vessel built on the Clyde up to that time. The only difference between the *Conte Rosso* and the *Conte Verde* is that the latter has the super-structure considerably strengthened and embodies a slight re-arrangement of the passenger accommodations by the introduction of a few more special cabins de luxe.

She is 591 feet in length over all, 570 feet between perpendiculars, 74 feet in breadth, 40 feet in depth to shelter deck, 26 feet load draft, of 18,000 gross tons, 20,000 indicated horsepower, and 18½ knots speed. She has accommodations for 230 first class, 290 second class, 1,880 third

The propelling machinery consists of two sets of Parsons compound double-reduction geared turbines supplied with steam by six double-ended and two single-ended boilers arranged to burn oil fuel but capable of being changed over rapidly to the use of coal.

SHIPBUILDERS' ACTIVITIES.—At the recent annual meeting of the Atlantic Coast Shipbuilders Association, the secretary briefly traced the organization's achievements mentioning among others its unremitting campaign for development of the American merchant marine, for the stabilization of private employment relations, for improvement in our immigration policy, and its constant insistence that the Government shall not compete unfairly with private business

Economy in Ship Repairs

By Robert W. Morrell, M. E., Marine Superintendent,
Tide Water Oil Company, New York

SHIP repairs fall naturally into four principal groups:

1. Repairs required for the economical performance of the vessel, such as cleaning and painting the underbody to maintain the speed without undue expenditure of fuel; boiler cleaning to secure proper boiler efficiency; renewal of packing to prevent wastage of steam.

2. Repairs required for safe operation, such as hydrostatic boiler tests, periodical classification surveys, compass adjusting, etc.

3. Repairs due to ordinary wear and tear; the maintenance of the vessel in good condition, to prevent undue depreciation or deterioration. For example, scaling and painting the steel hull, keying up of machinery, renewal of zinc plates, and the like.

4. Break-down or damage repairs; the repairing or renewal of parts due to breakage through carelessness or accident, collision, grounding, heavy weather or fire damage repairs.

Obviously, many repair jobs may be classed under more than one of these headings, but the above grouping forms a convenient basis for analysis in any constructive effort to reduce repair costs. By reduction in repair cost

is not meant keeping the repair bills low at the expense of other operating costs. Superintendents have been known to incur extravagant repair bills but by charging them off to capital account, depreciation, stores, insurance or other accounts, claim a wonderful showing on low repair costs. This is of course false economy, and it is necessary to recognize the broad principle that repairs are incurred for the good of the ship as a whole, and that, while it is important to minimize the repair account, any repairs are justified which will reduce the general operating expense. Repairs are repairs, no matter what else they may be called or how charged on the books, and we must avoid any mistaken sense of security in believing we have attained efficiency through low repair bills, so long as the money is going out under another name, without ample justification. It is therefore necessary to consider the repair question from all angles in order to exercise the most thorough supervision.

This article considers the subject of steamship repairs from a broad viewpoint in its relation to the general scheme of steamship operation. Repairs constitute an important factor in the operating costs and have an effect upon the other items in the voyage accounts which must be thoroughly analyzed and taken into consideration, if we are to achieve the maximum efficiency in operation.

The question of just what constitutes repair charges is often difficult to define. The renewal of boilers, pumps, hull plates, or machinery parts, if they increase the value of the vessel, is en-

titled to be charged, in part, to the capital or investment account. The use of paint is directly attributable to the maintenance and upkeep of the vessel, which is one phase of repairs, yet paint is frequently (and quite properly) charged to ship's stores. Renewal of spare parts, and machinery and oil burner parts in general, which are replaced regularly due to wearing out, are frequently bought from the manufacturer and charged to stores; but if the same parts were furnished by a shipyard in the course of a repair job, they would be charged to repairs. It is rather immaterial just how these items are handled, so long as they are all taken into full consideration and not lost sight of in attempting to economize on repairs.

The Interstate Commerce Commission has made rulings governing the method of charging repairs on vessels under its jurisdiction. This is for the purpose of fixing rates for common carriers, however, and does not always apply to the conditions encountered in overseas trade.

It is quite customary to set up a repair reserve account in an attempt to estimate and distribute the repair expense uniformly over the life of the ship. This is good judgment, as it provides a sinking fund to meet the heavier expenses of renewals of worn-out parts when the ship gets old. Such a reserve may be estimated roughly at 15 to 18 cents per deadweight ton per month for freighters, but is of course a matter for individual opinion. This reserve is usually adopted in estimating operating costs for proposed voyages. It is important, however, to avoid a false sense of security if the actual repairs amount to considerably less than the reserve provides for in a given period; they ought to, especially in the early years of a ship's life. It is the actual repairs which eat up the profits, and one cannot afford to sit back with a sense of satisfaction just because the actual repairs make a fine showing in comparison with the repair reserve. We must be eternally on the alert in handling the actual repairs.

Repair expense and depreciation have a relation to each other which should not be lost sight of. A vessel which has been kept in good condition can be sold after a period of years for more money than a vessel on which little or nothing was spent for upkeep. Therefore, a greater expense for maintenance will reduce the actual depreciation, and a clear conception of these relative values will go a long way toward intelligent control of the repairs. As a general principle, however, it may be said that excessive expense toward keeping a vessel in top notch condition will seldom be recovered in the selling price; therefore the expenditure for maintenance should be limited to the amount necessary to keep the ship in efficient operating condition and to avoid premature renewals or replacements.

One of the chief items to keep in mind in fixing a policy for supervision of repairs, is the importance of the time element. Unfortunately, this is often lost sight of, especially on freighters spending two or three weeks in port discharging and loading cargo. On such vessels, the idea too often prevails that a day or two more or less doesn't matter, where as an actual fact a day's expense is just as great on such a vessel as on one in port only a day or two. Every day spent in port is non-productive, but the overhead is going on just the same: depreciation, insurance, wages, provisions, stores, repairs, port fuel.

The marine executives of the United States are now entrusted with the greatest fleet of merchant ships in the history of the nation. The question of ship subsidy is for the present a closed book, and we can only turn to our task and face the future with the determination that, left to our own resources, we will spare no thought or effort, and leave no stone unturned, in making the most of our maritime inheritance and make the American merchant marine an example of intelligent and efficient operation.

The value of time of course depends somewhat on the valuation of the vessel, as the principal items of the overhead are the depreciation and insurance. The war priced ship, at \$200 per deadweight ton, has a tremendous handicap in this respect compared with the ships bought recently at \$35 per ton. Nevertheless, this overhead, whether big or little, goes on every day, and each day spent needlessly in port is a definite loss to the owner, whether the turn-around is 2 weeks or 2 days. On a freight steamer, where repairs can be carried out while cargo is being handled, there should be no excuse for the vessel being detained in port for repairs other than dry-docking or possibly repairs to cargo handling gear. Should such items arise, every effort should be concentrated upon such repairs with a view to quick completion.

The daily out-of-pocket expenses for overhead, etc., should be kept constantly in mind, as this is the only determining factor in deciding to what extent overtime on repairs is justified. It also determines many other points, such as whether it is cheaper to send a vessel to a shipyard for repairs or send the repair men to the ship at the berth; also, whether it is cheaper to furnish steam from shore or tug for discharging in order to effect boiler repairs simultaneously, or cheaper to repair the boilers after discharging. The time element is the deciding factor in every case.

and too great stress cannot be laid upon the necessity of attaching full importance to the value of vessels' time, in handling their repairs.

This emphasizes the previous statement that repairs must be handled for the good of the ship as a whole, as much as for showing cheap repair bills. It is often necessary to incur heavy repair expense to obtain prompt dispatch, but overtime, extra shifting, shore steam, and other expensive items, are well justified, if they really show sufficient saving of the ship's time. These expenses are sometimes good economy. This will be mentioned again in connection with repairs on ships operating on quick turn-around.

Work done on upkeep and repairs is invariably cheaper, if done by the ship's crew than by shore labor, and the signing on of extra sailors, oilers or wipers is therefore often good economy. A good carpenter or a good machinist on board will do a great deal towards keeping repair bills down. Workshop machinery, shop tools, and any repair materials within reason, are an excellent investment on shipboard.

SPARE PARTS TO BE CARRIED

The list of spare parts to be carried on board deserves careful thought, in order to have the right parts at the right time, without carrying a needless amount of "junk." It is far better to have too many spares than too few, however. The principles to keep in mind in selecting spares are:

- (1) What might be needed in case of breakdown at sea?
- (2) What would be most useful to provide against breakdown at an out port?
- (3) What parts could not be obtained quickly in the home port without great expense?

A judicious selection of spares will often save many thousands of dollars on a single item. The question of spare parts is a complete subject in itself, and one which vitally affects the repair situation.

Some repairs, of course, cannot be done by the ship's per-

onnel, and the mates and engineers should be instructed to have clear, complete lists made out upon the arrival in port, showing the work required to be done by a repair yard. The lists must be complete as possible, as it is uneconomical to discover forgotten items just before sailing or even in the middle of a repair job, when too late to obtain bids. A considerable saving in time and money can be affected if these lists are presented by the ship so worded and in such detail that they can be used as specifications in obtaining bids, without having to be re-written and revised.

REPAIRS DUE TO CARELESS HANDLING AT SEA

One of the best ways in which to cut down repair expense is to eliminate the mis-handling of machinery and equipment, and this is a very definite point in which the ship's officers can prove their worth.

A great many repair jobs are purely the result of careless handling at sea, and this is an item of repair cost which can be eliminated at its source. I have in mind the burning out of breechings and uptakes through improper burner and draft regulations, furnace crowns coming down through careless filtering, condensers ruined through lack of rinses, cylinder liners scored and piston and rod packing ruined through a high water-level.

Another source of economy in repairs is to do away with unnecessary alterations which cater to individual fads. A company should have a certain well-defined standard system of connections for

auxiliaries, lay-out of pipe connections, etc., and should adhere to some uniform scheme based on good practice, rather than sanction an infinite variety of pipe connections, and constant alteration of same, to suit the changing ideas of the men in charge. Before making an alteration, it is always advisable to consider how long the ship was running the way she was, and how much of a detriment the item under consideration was to her efficiency. One must exercise judgment, and combine conservatism with progressive initiative, but above all, one must think, not only twice but three or four times, before spending money on repairs.

SHORE STAFFS SHOULD KNOW THEIR SHIPS

It is up to the shore staff to know their ships. The home office should have not only detailed specifications and blueprints of all their vessels, but particulars of all auxiliaries and equipment, giving make, sizes, serial number, etc. There should also be accurate records of dates of last dry docking, United States Inspection, classification surveys, boiler washing, tube sponging, hull scaling, etc., as well as a record of the repairs done to each part of the ship at various times. It is only by having complete and accurate information kept up to date and quickly available that a superintendent can exercise proper supervision over the repair situation. A vessel may be detained a day or two in an outport and, by referring to such data, it might be arranged to take advantage of that time to do some much needed scaling on the bottom or, to carry out some other work that at another time would interfere with the vessel's schedule.

It is also necessary to know at all times just how much re-

pairs are costing on each ship, not only as a whole but for various sub-divisions such as:

Boiler repairs,
Main engine repairs,

Dry docking,
Hull scaling.

This list can be continued indefinitely, and it is useful, if one sub-heading appears high, to sub-divide it still farther. For instance, if boiler repairs seem too expensive, divide it into:

External cleaning,
Internal cleaning,
Mountings,

Calking,
Renewing or repairing tubes,
Renewing or repairing stays.

In this way the item where the financial leak occurs can be traced down and the condition remedied. In keeping such cost records, however, do not rely on your cost department for periodical figures but keep your own record, based on bills approved.

It is decidedly worth while for the shore staff to do their own estimating and to become trained in that line, and this is something to which sufficient attention is not given today. It is quite essential to know what each repair item will cost before authorizing it. Many times, if we realized in advance how much a repair job was going to cost, we wouldn't consider the expenditure justified, and we wouldn't do the job at all, or we would figure out some other and cheaper way of doing it.

An estimate of his own frequently enables a superintendent to handle a job on an agreed price without wait-

ing to call for competitive bids. If a job is done on a time and material basis, such a preliminary estimate gives a good idea as to whether the bill is reasonable. On the other hand, if bids are called, the preliminary estimate may show the bids are all high and it would be cheaper to do the job on time and material.

This brings up the question of taking bids and placing a contract, or working on a time and material basis. There are arguments on both sides, and many features to be taken into consideration, so that the best policy usually depends upon the circumstances at the time. Naturally, on a rush job, with no time to spare, time and material is the best basis; but with time available in which to prepare complete specifications, there can be no doubt that the best results, on the majority of repair jobs, can be obtained by competitive bids and a contract. This implies, however, a first class specification and a thorough inspection. On time and material, the specification is not so important, but inspection is equally necessary and in addition a checking or time-keeping system becomes necessary, and is an added expense. Time and material is in fact the old "cost plus" system, with no end of opportunity to slip in extra charges for foremen, shop tools, lights, excess material, and other items very difficult to check. If time and material basis is used, it is best done by billing actual labor and material plus an agreed fee.

SPECIFICATION SHOULD BE COMPLETE AND ACCURATE

A loose specification is worse than none at all on a contract job, and every effort should be made to have the specification on which bids are called as complete, accurate and specific as possible. If indefinite, the bidders can only pro-

Time is an ever-present and all important factor in ship economics. Every day a ship lies idle, through lack of forethought or initiative or energy on the part of the operator or Master, is a dead loss, an expense without an earning, a black mark against any record of achievement. Indifference to the value of time of our ships in port is one of our worst faults. Time is money, and equally slippery. Too many delays, if analyzed, could have been avoided by exercising a little snappy supervision. Repairs are a fruitful source of delays, frequently unnecessary delays, and offer a wonderful opportunity for economizing time. Don't blame your delays on the repairs. Handle your repairs so there are no delays.

fect themselves by including an amount to cover contingencies left open by the vague wording, so that the bids are higher than the job is worth. All such phrases as "repaired or renewed," or "as may be directed," or "to suit conditions," or "to owners' approval," or "as may be found necessary," should be eliminated unless the meaning is perfectly obvious when looking at the job.

An incomplete specification is the most expensive thing to contend with. Items left out or forgotten have to be done after the contract is awarded, at the contractor's price.

In many cases it is impossible to tell in advance whether certain work will be required, until the job is opened up. In such cases, separate prices should be taken, which can be authorized or not later on as the conditions indicate. Do not include an uncertain item in a specification for fear it will be forgotten. If in doubt whether it will be needed, get a separate price on it. These separate prices may or may not be taken into consideration in awarding the contract, depending on the likelihood of having to carry out such separate items, but at least the separate prices give a good protection, if the work materializes.

Inspection should be well organized. The shore staff should make thorough inspections of the ships while in port, to keep in close touch with their physical condition. The inspection of repairs in hand by a shipyard should be divided between the ship's personnel and the shore staff, with all possible co-operation. On engine room work, the chief engineer should inspect and approve, before closing up, all work on machinery for which he is responsible. The port engineer should likewise maintain a supervisory inspection in order to insure uniform general practise on all vessels of the fleet.

We need closer co-operation between deck and engine departments on shipboard, and between the ship's personnel and the shore staff, in order to get results. All hands are working toward the same end, with a common interest, and those who cater to petty jealousies and mutual obstruction are only standing in their own light and casting a shadow upon the whole profession as well. The home office is usually in a position to get a broader view of a problem or policy than any individual master or engineer, but the sea-going men are better acquainted with their vessels than anyone ashore could hope to be, and their opinions and suggestions should be given every consideration.

SAVE MONEY BY PLANNING AHEAD

Work can be planned ahead to advantage, laying out a dry docking schedule clear of the winter months. Painting in dry dock in freezing weather is usually a total loss. This schedule should also coincide as far as possible with United States inspection and classification survey periods in order to cover everything possible in a single lay-up. It is also worth while to plan in advance to bring about the dry docking, United States inspection and survey in the home port. All repairs can usually be done to much better advantage in the home port, under direct supervision. Repairs in foreign ports are subject to heavy duty.

It is often advisable to let minor repairs accumulate until a dry docking period, as it is cheaper to carry out a group

of items in one contract than to do each small item at a time provided there is no operating loss involved.

The handling of repairs on vessels maintaining a quick turn-around schedule, such as tankers, bulk freighters which load and discharge rapidly, and certain passenger liners represents the highest form of management that demands a well balanced combination of judgment and "pep," and brings out many valuable lessons. The time element becomes magnified, and attention is centered upon maintaining schedule with only a day or two in port at each end and with a minimum lay-up period for overhauling.

QUICK TURN-AROUNDS CALL FOR EFFICIENT MANAGEMENT

It becomes necessary to exercise judgment in determining where to draw the line between driving a ship in continuous operation, and losing time to keep her up. The ability and willingness of the ship's officers to perform their own upkeep and repairs becomes a vital factor. Overtime and other expensive measures become a source of economy in saving time. A well defined policy is essential, and advance planning becomes necessary.

Boiler washing looms up as a determining factor in the planning, and must be handled, if possible, by washing one boiler each time in port. Dry docking, annual inspection and periodical surveys must be combined, if possible. On rush jobs there is seldom time to get bids, and frequently a working agreement with a convenient repair yard is the best policy on rush work.

In order to achieve any sort of operating efficiency it is first necessary to impress upon the masters and deck and engineer officers the fact that it is only through their whole-hearted efforts that our vessels can be kept in operation at all; that unless the vessels are handled with best possible dispatch and minimum expense, they cannot make ends meet and will have to be scrapped. Our officers must understand the value of the time element and must make every effort, first, to keep their ships in first class condition without the assistance of shore labor, and, second, to carry out themselves the bulk of the ordinary repairs, such as keying up, boiler washing, etc. By taking keen interest in details of their ships, the officers can effect valuable savings.

Arrangements should be made, however, for a vessel to radio ahead her repair requirements, and the shore staff should know the vessels well enough to draw up a specification in sufficient detail to obtain bids while the vessel is still at sea, so the contract can be awarded and the repairers meet the vessel upon arrival. It is also common to run repair a voyage ahead; namely, when a ship is in port this time determine the repairs needed next time and get the bid in, so the job is in hand the minute the ship arrives back. Repairs are often postponed from one voyage to the next when feasible, to avoid a Sunday or holiday job, and there is great advantage in allowing minor items to accumulate until dry docking. The whole scheme of repairs in quick turn-around brings out the fine points of efficient management.

HYDROSTATIC BOILER TEST EXCESSIVE

One important factor bearing upon repair economy is the annual hydrostatic boiler test. There is great diversity of opinion as to the advisability of the high test pressure required by law. Most authorities are agreed it is excessive but hardly any two agree on the remedy. The fact remains the test pressure is often responsible for boiler leaks and extensive repairs which would not have occurred otherwise. The writer's opinion is that the test pressure should be reduced and a classification certificate accepted in lieu of boiler test. Until some change comes about, however, the only logical course is to exercise every possible precaution in handling the "squeeze" to avoid damage; namely, (1) very uniform building up of pressure, (2) proper adjustment of gages and safety valve springs in advance to avoid repeated application of pressure, (3) holding the pressure only an in

ant, (4) gradual release of pressure, (5) temperature precautions.

DAMAGE REPAIRS

With reference to damage repairs, i.e. collision, grounding, heavy weather and fire damage, this usually constitutes an insurance claim. There exists an impression that it is economical to hang as many repair charges as possible on the underwriters; but as this is reflected in future premiums, the advantage is likely to be only temporary, if carried to excess, aside from the moral aspect, which is not within the scope of this article. A damage job usually involves many complications of a highly technical nature, and as the hull insurance entitles the vessel to the services of a surveyor at underwriters' expense, it is frequently wise to take advice from a surveyor specializing in this line. The possible variation of difficulties in these cases is too great to cover here, but a general idea of the terms of the policy and a clear conception of the following features should be had by anyone handling steamship repairs:

1. What constitutes a franchise under the policy.
2. Temporary repairs—when and how justified, and when chargeable to underwriters.

3. Disposition of charges for towage, steaming and cleaning tanks, removal and replacement of bunkers, etc. Allowance for diversion to port of refuge.
4. Element of time as applied to collision cases as distinct from other cases.
5. Relation between classification and underwriters' requirements.
6. Protest and certificate of sea-worthiness.

The American Underwriters can contribute their share toward the economical repairs and operation of the American merchant marine to which they owe their existence, by maintaining the highest caliber of men in their executive and technical staffs. It is only by highly intelligent handling of damage repairs and claims that efficiency in this direction can be maintained.

What can the repair yards do toward repair economy? It is to their interest as much as that of any one that our ships be kept in operation, and they must be alive to the fact that they can contribute to that economy of operation without which there can be no existence for the ships or for them. It all boils down to a matter of mutual cooperation. Live and let live. Live and help to live. Play the game on the level. High class efficiency and service will win out.

Efficient Repair Methods Adopted by Shipping Board

By Captain R. D. Gatewood*

Work your crews up to take pride in their vessels; watch the method under which the repair work is awarded; know what the repairs should cost; be sure you have the proper port staff—and then your repairs should cost the minimum.

A SELF-EVIDENT fact is that the successful ship operator is one who, beside filling his vessels, keeps the cost of his vessel operation at the lowest figure. No matter how efficiently or industriously his traffic men work the bottoms, if the result of their efforts is to be turned into a deficit by the losses of physical operation of the vessels, then there is no hope for a paying proposition. This article will deal only with vessel repair costs, and will illustrate to you the enormity of this item there is below the approximate percentage of the cost of physical operation of the Shipping Board fleet:

Operating Divisions.	Percent.
Repairs (including insurance repairs).....	13
Fuel	25
Subsistence	7
Wages and overtime	24
Supplies and miscellaneous	8
Port charges	9
Cargo charges	14

In the general item of repairs are included the following items, with the percentage of the total set opposite each:

Classes of Repairs.	Percent.
Maintenance (voyage repairs)	50
Alterments and alterations	11
Reconditioning	10
Insurance repairs	18
Operation of vessels expense (which includes items such as installing grain fittings, cattle fittings, repairs to navigating instruments, rigging, tackle, etc.)	11
Total	100

The "maintenance" item is wholly chargeable to repairs, is also the greater part of "operation of vessels expense." Alterments and alterations" and "reconditioning" of course

*Director of maintenance and repair, United States Shipping Board, New York.

are capital charges, while "insurance repairs" in the privately owned fleets are not usually paid by the owner but by the underwriter.

The expenditures of the Shipping Board for the general item of "repairs" since 1919 are listed on page 348.

A basis of cost per deadweight ton per month per mile would of course be a fairer basis of comparison, but the large number of vessels operating does not permit obtaining such a figure without undue labor.

An analysis of these figures will indicate a gradual decline in the cost per deadweight ton. This is not an altogether natural decline. The cost in 1920 was staggering and the problem was thoroughly studied from all angles. It was realized that there could be no sedative adopted that would solve the problem in a few months. Whatever was to be done should be so planned that the correction of past practices would be gradual and those concerned would be educated in these policies one after the other when they were ready for them.

There were many self-evident causes of this large expenditure, chief among which were the performance of many alterations which were purely the individual ideas of the ships' crews; the failure of crews to perform repairs that properly should be handled by them; indifference of crew in operation of vessel; inexperience of vessels' personnel; inadequate and inefficient port staffs; high cost of labor and materials; shortage of skilled ship workers; irresponsible repair firms and inefficiency of repair yard organizations; the cost-plus (or so-called "time and material") method of effecting repairs; and many other lesser causes.

Some of these difficulties would of course be straightened out by time alone. We could not govern the cost of labor and material. The curtailing of work and increase of production would solve that problem; irresponsible and inefficient

repair firms would wish by their own hand when the abnormal demand for work would cease; the workers would become more skilled with time and would take keener

MONTHLY STATEMENT OF SHIPPING BOARD EXPENDITURES FOR REPAIRS

Month	Expenditures	Tonnage in Service	Cost per DWT.
1920—January	\$4,787,082.30	8,008,178	\$0.59
February	5,417,507.00	8,426,784	.64
March	6,992,890.26	8,434,958	.83
April	6,571,170.50	8,715,063	.75

1923—January	2,057,157.35	3,517,155	.58
February	1,516,578.36	3,533,604	.43

*The comparatively large expenditures during these months were caused by preparing vessels from lay-up for active service.

**The large expenditure this month was due to payment of one bill for damage repairs of over \$500,000 which had been held in abeyance for a number of months.

interest in their jobs as there ceased to be a demand elsewhere for their services.

But many deficiencies were within our power to correct and our attack was planned along the following lines:

- A—Extend policy of competitive bidding to the practical elimination of all other forms of awarding work.
- B—Eliminate all alterations except the absolutely necessary ones.
- C—Carefully examine repair lists to eliminate all work found unnecessary or which could be performed by crew.
- D—Develop estimating, so that we would know the value of the work to be performed.
- E—Educate the crews to perform all work possible and take an interest in the property under their care.
- F—Insist on the maintenance by operators of efficient qualified port staffs.

Competition is the basis of a successful and healthy industry, so that the extension of this policy was not alone beneficial to the repair costs, but to the ship repair yards and allied industries as well. It has resulted in the elimination of the irresponsible, inefficient organizations who entered this business during the flood tide of war conditions. The ship repair industry is now stabilized, the market is highly competitive and the yards are approaching rapidly their pre-war efficiency.

The very marked decline in repair costs is due to this one thing more than to any other and now from eighty-five to ninety percent of Shipping Board repair work is placed after competition.

Two or three years ago, and to a lesser extent now, the idea was prevalent among the sea-going personnel that the vessels built during the war were exceedingly deficient. This led to an enormous number of requests for alterations and betterments which were mainly inspired in the above belief. Many of them were desirable but were they necessary? Many a man desires a particular make of automobile, but if he cannot afford it, buys a cheaper one. And you can be sure that he makes that one operate to his satisfaction because it is his property. So, the bars were placed against alterations, except where we were convinced that they were absolutely necessary for the proper operation of the vessel, and the protection of life.

The idea seemed to be prevalent among many of the crews that the sole object of placing them on the vessels was to keep the vessels moving from port to port. They took little or no interest in it, feeling that any repairs developing could well be taken care of by shore gangs. Anyway, it was Government property and they did not care if it depreciated although they were joint owners with you and me. But this was not the proper spirit to display.

Could a successful merchant marine be developed with such a feeling? No, and that is why we insisted on vessels crews performing all work properly belonging to them. This has been so inculcated in the crews that we now have relatively few requests for work to be performed by shore forces that could properly be done by the crew. Of course, the increasing experience of our crews has helped, but the average crew now have a greater interest in their vessel and feel to a greater extent that it is their home. Until the spirit of pride in their ship is developed to its maximum among our sea-going people, our merchant marine cannot achieve outstanding success, but great progress along this line is evident to us through the barometer of repairs.

Why do you go to an assayer to have him determine the value of your precious metals? Because you have confidence in his judgment and determination of these values. Accordingly, why should we place repair work in hand without knowing beforehand the value of that work? We have therefore employed and developed in our organization men qualified as estimators, who have full knowledge of the ship repair market and who know what a job is worth. We have in this way rejected bids that were excessive as compared with our estimate and have later obtained more reasonable prices.

A number of vessels under one company without proper technical direction cannot operate to the maximum of their efficiency. Accordingly, we have insisted that the operator have on their port staffs men whose efficiency and knowledge of their business are unquestioned and men who are of the proper port staff type—men in whose good judgment and knowledge of the business the crews cannot help but impose confidence. To my mind the keystone of successful operation rests on the selection of the proper port staff, for with the proper port staff the selection of the proper crews is assured and the maintenance of efficient operation by them is inevitable.

I cannot too urgently recommend American ship operators to pay close attention to the repair of their vessel. As I have said before, this item is one which may cause a large loss in your operating revenue and may determine the side of the ledger on which the balance will show.

The Shipping Board has greatly decreased its repair costs. The methods employed were dictated only by common sense and knowledge of the repair business. They were no revolutionary in any sense. We simply watched our property, sought the leaks, and repaired them. You must grant that with such a large operating fleet as that of the Shipping Board, such efforts were vastly more difficult than would be those of the average private shipowner.

Let your motto be, "Watch the Repairs."

Does It Pay to Have a Satisfied Crew?

By Captain John F. Milliken*

Sooner or later our shipping men will discover that the cheapest men are not always the most economical and that a satisfied crew pays real dividends. The best way to arouse a real interest among the officers and crew is to encourage the men to purchase a few shares of stock. As stockholders of the company most men take a decidedly different view of things.

ALTHOUGH much time and money have been spent by steamship owners and operators in studying problems affecting the shipping industry, the people at the head of the industry in this country have lost sight of one very important, vital fact. The economic operation of ships depends first, last and at all times on the personnel. The finest equipped ship in the world could not be run economically unless the men in charge of the vessel had intelligence and took a real interest in their work and co-operated all the way down the line for economical operation. The leaders of the shipping industry in our country might well bear a page from the records of some of the successful industrial leaders on shore. Many of these most successful men have dropped the autocratic method of handling their help and in various ways have succeeded in making their employees happy and contented.

Conspicuous among others, the United States Steel Corporation is making an effort to meet their employees half way. On the Great Lakes they operate a large fleet of vessels in the ore carrying trade and on these lake steamers the operators for the United States Steel Corporation treat their officers and men with the utmost consideration.

They are paying their officers a little more than the regular lake wage. They furnish the crews with excellent food, supply books and take an interest in any man who is injured or sick while in their employ. The captains of the various ships are consulted in regard to any change in policy affecting their ships. They are called upon to give their opinions as to whether certain men should be retained in the employ of the company or not, when such a man has been in an accident or has had other trouble, and in many cases they are made to feel that they are a part of the scheme of things. It would be hard to find a more loyal or efficient group of men than those who are employed on the steamers of the United States Steel Corporation on the Great Lakes.

This company also operates ships on the salt water where their men are treated, as a rule, with real respect and consideration but co-operation between the company and the men has not been developed to the same stage of perfection which prevails on the Great Lakes.

Secretary-treasurer, Neptune Association, New York.

The Standard Oil Company is another company which has taken cognizance of the welfare of its employees. This company has developed a bonus system whereby the employees are rewarded for efficient service. They are also permitted to purchase a certain amount of stock in the company. The employee pays for half of this stock and the Standard Oil Company pays for the other half. The amount of money which the man pays is deducted from his pay each week and after a certain period of time the employee becomes full owner of his shares.

The plan of paying a bonus met with instant approval on the part of the men on the ships. Every man of the crew on a Standard Oil tanker is entitled to a bonus, if he remains on the ship a year. The Standard Oil Company decided some time ago that it was much cheaper to pay a man a bonus and to try to keep him satisfied with his conditions so that he would stay aboard a ship than it was to change the crews every trip. It is very easy for a new man on an oil tanker to turn the wrong valve and mix up a cargo of oil, or to stop the flow of oil into a tanker and break a pipe line and lose great quantities of oil overboard. Since the bonus plan has been in operation there have been very few changes of masters, chief engineers and first mates. The men are satisfied with their jobs, stand by the ships and they give the Standard Oil Company excellent service for their investment.

This company, it is true, is a little differently situated than most of the regular steamship companies. It is not necessary for them to chase all over the world for cargo and they are not dependent entirely upon shipping for their income.

BIG STEAMSHIP COMPANIES DISREGARD EMPLOYEES

The big steamship companies in this country believe in exercising autocratic power over the men who work for them. Some of the owners pay the men the smallest possible wage that the traffic will bear. When it is necessary for a man to accept these small wages, in almost every instance he makes up his mind to stay on the ship only long enough to make a few dollars. In the case of an engineer, if he is aboard only for one trip, he will not do any more work than is absolutely necessary and he is liable to neglect very necessary things by "passing the buck" to the man who will relieve him. The same thing is true of the deck department where

Captain J. F. Milliken

cargo plans have been lost and freights greatly confused by the changing of the deck officers. This continuous changing of crews is a costly thing and the lack of co-operation and understanding has cost steamship owners large sums.

It is easy enough for the shipowners at this time to disregard the men who work on the ships and to cut wages to such a low figure that it is impossible for the men to maintain a home ashore. If this practise continues, it will be the death knell of American shipping and no amount of subsidy or other aid will be able to save it.

SELECT BEST COMBINATION OF NATIONALITIES IN CREW

The personnel question on American ships is a more difficult problem than in other countries. Here we have a personnel which is composed of people from almost every nation on earth, and for that reason much careful study should be given to this very important phase of the shipping industry. The people who go to sea are human just the same as the people who stay ashore and, while many of the men who sail in our ships have become citizens, in many cases they retain their national characteristics. All of the officers are American citizens, or were after May 7, and as American citizens one man should have as much right as another. The spirit of fair play should prevail and for the good of everybody concerned the wise owner should make a study of what combination of nationalities work together to the best advantage of everybody.

From personal contact with troubles which have developed aboard ships, I have discovered that it does not pay to put an American captain, who originated in Great Britain, in command of a ship where the three mates originally came from Norway. In reviewing the cases of many seafaring men who are on the "deferred employment list" of the United States Shipping Board, I have noticed that much of the trouble was apparently caused by placing a man in command who had no sympathy or understanding with his officers. The lack of co-operation on ships which have been manned in this way has cost the Government a great deal of money.

UNJUST TREATMENT BRINGS RETALIATION

The captain of a ship has a responsible position. He is a buffer between the owner and the men, and in many cases he is made the goat and is forced to pay for something over which he has no control. In one case the captain of a ship was fined \$100 because one of the engineers had pumped fuel oil into the harbor at Norfolk while the captain was away attending to the ship's business. The captain paid the fine and then tried to collect the \$100 from the owner, who flatly refused to pay.

Making the captain pay \$100 for an act for which he was in no way responsible killed all the co-operative spirit which he may have possessed previous to this incident. To get even with the owners he hired a pilot in every port where the ship entered or cleared. He was making a voyage to the West Coast and held pilot licenses which would entitle him to pilot his own ship into several of the ports but he was not in the humor to save money for the owners, even if it had been possible for him to do so. He also hired two tow

boats to dock his vessel when it might have been possible for him to get along with one, and, if the vessel finished loading or discharging during the night, this man would not leave the dock as he was accustomed to do but would wait until the next morning and sail at daylight. On a voyage to the West Coast and back this same captain spent probably a thousand dollars which he might easily have saved, as he arrived in New York two days later than he would have arrived if he had been pushing his ship all the time. The owner, in this particular case, saved a fine of \$100 but paid many times that amount for the lack of understanding and knowledge of the captain's duties, besides creating a feeling of distrust in the mind of the captain.

Another instance occurred where the operators made a special concession to obtain a contract to carry 2,000 tons of print paper to South America every month. On the first voyage over 12 percent of the paper was damaged due to poor stowage and rough handling. On delivery of the second cargo the damage was so great that the contract was cancelled and the company lost about \$3,000 where they should have received a substantial profit.

The officers and crews on the ships, as well as the stevedores, evidently lost sight of the fact that ships are paid to carry and deliver cargoes in good condition and that if this is not done the operators earn nothing. I know instances where the carelessness has been so flagrant and the damages so great that one could almost

imagine that crews had been planted on the ship to destroy the trade.

If a business is always run at a loss, there is no money for employees, the company goes out of business and a number of positions are destroyed. The men should take an interest in their work and use every effort to put the American merchant marine on a paying basis. The best way I know of to awaken a real interest is to encourage the men to purchase a few shares of stock. As stockholders in the company most men take a decidedly different viewpoint of things.

STEAMSHIP OWNERS LACK VISION

I have been lead to believe that the present day steamship owners and operators have no vision when it comes to a question of personnel. It appears as if they were looking only for the profits of today and were making no effort to build up for posterity. At the present time there is absolutely no agreement of any kind between the owners and the crews of their ships. Some of the owners who have charitable hearts contribute generously to various institutions which are supposed to be maintained for the benefit of seafaring men. Some of these institutions are really charitable in their operation, but charity is not understanding and the majority of the seafaring men do not want something for nothing. Charity destroys a man's ambition, ruins his independence and kills his sense of responsibility.

It is a well-known fact that the steamship owners and operators in this country have many very trying and difficult problems. They are courageously battling against conditions which are much worse than any others which have ever been encountered in this or any other country before.
